CASE NOTES

TERATOMA OF THE ORBIT*

BY

N. S. JAIN AND R. C. AGARWAL

Department of Ophthalmology, Irwin Hospital, New Delhi, India

Orbital teratoma is an exceedingly rare congenital neoplasm, there being only one other case previously reported from India (Kirwan, 1935). Only sixteen other cases, fourteen reported by Duke-Elder (1952), one by Kamel (1954), and one by Girard, Fountain, Moore, and Thomas (1958), have been found in the literature.

The following case is therefore of interest because of the extreme rarity of this tumour.

Case Report

A female baby, seen when one day old in June, 1957, had a large mass protruding from the right orbit (Fig. 1).

The cornea could be identified but other ocular details were obscure. The skiagram showed a wide and shallow orbit. Exenteration of the orbit under a general anaesthetic on the third day was followed by an uneventful recovery, and the child is known to be alive at the present time.

Histological examination showed the tumour to be a teratoma (Figs 2, 3, 4, 5, and 6, opposite).

* Received for publication November 21, 1960.
TERATOMA OF THE ORBIT

Summary

One case of teratoma of the orbit is reported to bring the total of the recorded cases to seventeen.

Our thanks are due to Prof. L. P. Agarwal, Professor of Ophthalmology, All-India Institute of Medical Sciences, New Delhi, for arranging to supply the photomicrographs.
