Ocular disease in South West Africa

To the Editor of the British Journal of Ophthalmology

Sir,—The report by Jeffrey Freedman on ocular disease in South West Africa (Brit. J. Ophthal. (1973) 57, 681) is superior to most reports of this type in that the population studied is defined, data are reported by age and sex, and an effort was made to examine a representative group. Two comments seem appropriate.

It is difficult or impossible to know who may be representative with respect to ocular pathology (or any other characteristic of interest), and the very best way to avoid bias is to select at random. Since a preliminary house-to-house census was included as part of the study, it is most unfortunate that some procedure was not utilized to select patients for examination. When the investigator chooses subjects he thinks are representative, he may succeed or he may fail by a wide margin. There is no way to judge. Random samples are not only unbiased, but the probability that the sample findings deviate by a designated amount from the underlying population is readily calculable.

The common mix-up between prevalence (cases existing at the same time of the examination) and incidence (new cases occurring during a specified time period, such as a year, without regard to whether they have been cured or are otherwise not present at the end of the period) is maintained in this paper. The summary paragraph refers to “a survey of the prevalence...”. Elsewhere the paper refers to “the first account of the incidence...”. In fact the paper provided only prevalence data.

Yours faithfully,

HAROLD A. KAHN
Chief, Office of Biometry and Epidemiology

To the Editor of the British Journal of Ophthalmology

Sir,—I should like to thank Dr. Kahn for his constructive criticism. As regards random selection, this was not total but did apply to a certain extent, as patients that we have seen at the clinic were not selected but came at random. The reason for the census was to ascertain an idea of the age distribution in order to avoid the circumstance of bias towards any age group. I do agree that this negates random selection to a large degree. I must agree with Dr. Kahn’s criticism as regards the terminology of incidence and prevalence, as I did report only prevalence and not incidence.

Yours faithfully,

JEFFREY FREEDMAN
