Pigment dispersion syndrome and pigmented pattern dystrophy of retinal pigment epithelium

EMILY Y. CHEW AND AUGUST F. DEUTMAN
From the Institute of Ophthalmology, Nijmegen, The Netherlands

SUMMARY The 2 rare entities, pigmentary dispersion syndrome and pigmented pattern dystrophy of the retinal pigment epithelium, were found in a young male patient. Visual function was undisturbed.

Pigmentary dispersion syndrome is a rare entity found mainly in young myopic men. It is characterised by Krukenberg's spindles on the posterior corneal surface, loss of the pigment epithelial layer of the peripheral iris in a radial slit-like pattern, and deposition of pigment in the trabecular meshwork and peripheral lens surface and the anterior surface of the iris. In some cases of pigmentary dispersion glaucoma may occur. Since the original publication the characteristics of the disease have been well described. This paper is a case report of a patient with pigmentary dispersion syndrome presenting in addition with a pigmented pattern dystrophy of the retinal pigment epithelium. We believe this has not been previously reported.

Case report
A 34-year-old male presented with complaints of slight dimming of vision in both eyes for 4 weeks. No complaints of 'haloes' were made. His general health was excellent. On examination his visual acuity was 6/6 right eye and 6/9+ left eye (with plano right eye, −0.50 sphere left eye). Slit-lamp examination revealed bilateral Krukenberg's spindles (Fig. 1) with iris atrophy peripherally in a radial slit-like pattern (Fig. 2). Goldmann applanation pressures were 26

Gonioscopy reveals heavy pigmentation of the trabecular meshwork bilaterally. Gonioscopy disclosed bilateral grade 4 open angles with heavy pigmentation of the trabecular meshwork (Fig. 3). Funduscopy showed minimal cupping with healthy optic nerve heads bilaterally. Coarse pigmentary changes of no particular pattern were seen in the maculae of both eyes, with a decrease in the foveal reflexes (Fig. 4). Examination with the Goldmann 3-mirror lens showed the deep location of the pigments in the retinal pigment epithelial layer. The retinal periphery and the retinal vessels were normal.

On fluorescein angiography a readily distinguishable reticular pattern in the form of a fish-net was seen in both maculae symmetrically (Fig. 5). The pattern on the angiogram was more distinct than the colour fundus photographs. The polygons formed by the reticular pattern measured less than 1 disc diameter. The pattern blocked fluorescence, with no

Discussion

This young man presented with the typical findings of pigmentary dispersion syndrome with ocular hypertension. The glaucoma which often accompanies this syndrome has been thought to be caused by the pigmentary obstruction of and damage to the trabecular meshwork. The cause of the loss of pigment from the iris is obscure. Theories have ranged from congenital atrophy or degeneration of the iris to actual mechanical rubbing between the peripheral concave iris and the zonules.

Pigmentary dispersion syndrome is rare. Pigmented pattern dystrophy of the retinal pigment epithelium is also rare; it usually occurs in healthy persons without ocular or systemic diseases. The only exception is the occurrence of pigmented pattern dystrophy of the retinal pigment epithelium in patients with myotonia dystrophia. Pigmented pattern dystrophy of the retinal pigment epithelium may be sporadic. Of the cases which are familial we consider there are 2 major categories, based on the hereditary patterns: autosomal dominant and autosomal recessive.

It may be a coincidence that this patient presented with 2 different pigmented diseases. Embryologically, however, the pigmented cells of the iris are very similar to those of the retinal pigment epithelium. Both tissues are derived from the neural crests and both are formed of round clump cells with rod-shaped pigments concentrated near the nucleus. Could this patient represent a congenital or degenerative disorder of the generalised pigmented cells of the eye? The rarity of these disorders suggests their conjunction may be more than chance coincidence.

Mr A. L. Aan de Kerk made the photographs.
