Raised plasma homocysteine as a risk factor for retinal vascular occlusive disease

Abstract

Background/aims—A moderately elevated plasma concentration of the sulphur amino acid homocysteine is an independent risk factor for atherosclerotic vascular disease. Many of the risk factors associated with coronary, cerebral, and peripheral atherosclerotic vascular disease are common to retinal vascular occlusive disease but it is unclear whether elevated plasma concentrations of homocysteine are also associated with such disease. This study assessed the relation between retinal vascular occlusive disease and elevated levels of plasma total homocysteine (tHcy).

Methods—A retrospective case-control study involving hospital based controls and cases with retinal artery, central retinal vein (including hemiretinal vein), and branch retinal vein occlusions was performed. The relation between elevated tHcy, defined as a level greater than or equal to 12 µmol/l and risk of retinal vascular occlusive disease was examined.

Results—87 cases of retinal vascular occlusive disease including 26 cases of retinal artery occlusion, 40 cases with central retinal vein occlusion, and 21 cases of branch retinal vein occlusion were compared with 87 age matched controls. Mean tHcy levels were higher in all disease groups and this difference was significant in patients with retinal artery occlusions (p=0.032) and patients with central retinal vein occlusion (p=0.0001). When adjusted for known cardiovascular vascular risk factors, tHcy was an independent risk factor for retinal vascular occlusive disease (OR 2.85 (95% CI 1.43–5.68)).

Conclusions—Elevated tHcy is an independent risk factor for retinal vascular occlusive disease. Assessment of tHcy may be important in the investigation and management of patients with retinal vascular occlusive disease.

The rare syndrome of homocystinuria was first described in 1962 among subjects with mental retardation, ocular and skeletal abnormalities, and a high risk of thromboembolism.1 In such individuals whose plasma total homocysteine (tHcy) concentrations are greatly elevated (often in excess of 100 µmol/l), the underlying defect is usually one of inherited dysfunction of the enzyme cystathionine B-synthase (CBS).2 The observation of marked atherosclerotic-like lesions in two neonates with homocystinuria, one with CBS deficiency and one with a rare defect in cobalamin metabolism, led McCully to propose the hypothesis that homocysteine is a causative factor for atherosclerotic vascular disease.3 This hypothesis has been supported by evidence from many further studies demonstrating a significant relation between elevated tHcy concentrations and risk of venous thrombosis, coronary, cerebral, and peripheral vascular disease.4–8

Recently, it has become clear that apart from rare genetic defects which are associated with greatly elevated tHcy levels, certain nutritional deficiencies are important and common determinants of elevated tHcy concentration.9 In particular, plasma concentrations and dietary intake of folate, vitamin B6, and B12 relate inversely to the tHcy level.10 Supplementation with such vitamins lowers tHcy levels and may reduce vascular disease risk.10

While retinal vascular occlusive disease and coronary, cerebral, and peripheral vascular disease have a number of risk factors in common including systemic hypertension and smoking, the classic cardiovascular risk factors do not fully explain these relations.11–16 To date, little information exists about the possibility that elevated tHcy might increase the risk of retinal vascular disease.17–20 The present study was undertaken to assess the relation between retinal vascular occlusive disease and moderately elevated fasting levels of tHcy.

Subjects and methods

CASES

Using the records of the photographic department of the Royal Victoria Eye and Ear Hospital to identify patients with retinal vascular occlusive disease, a retrospective case-control study was performed. Eighty seven cases with clinical and objective investigational evidence of retinal vascular occlusive disease were studied including 40 cases of central and hemiretinal vein occlusion (which were considered together), 21 cases of branch retinal vein occlusion, and 26 cases of retinal artery occlusion (central and branch were included together). To minimise the influence of the vascular event on plasma tHcy concentrations and to reduce bias caused by risk factor treatment only cases diagnosed between 3 and 12 months before the study were included. Exclusion criteria were recent major systemic illness (including myocardial infarction), evidence of vasculitis, renal, hepatic, or thyroid disease, cardiomyopathy, pregnancy, psychiatric illness, chronic alcohol abuse, anticonvul-
sant therapy, and recent (within 3 months) exposure to nitrous oxide.

CONTROLS
Eighty seven hospital based controls were age matched and had no history or clinical evidence of retinal vascular disease. The majority of controls were patients attending for routine cataract extraction (n=59) while other controls had a range of surgical procedures including retinal detachment repair (n=8), trabeculectomy (n=7), ptosis repair (n=2), squint repair (n=1), secondary hydroxyapatite implant (n=1), and excision of pterygium (n=1). A smaller number of controls were hospital staff members (n=8). Exclusion criteria were as in the case group.

VARIABLES EXAMINED
Demographic, cardiovascular risk factors, and diagnostic data were recorded for each subject based on a standardised format. Diagnostic data consisted of biochemical, haematological, and endocrine variables that are known to alter tHcy levels. All blood samples were taken fasting (samples were taken preoperatively in controls requiring surgical treatment) and analysed using standard automated laboratory techniques. Blood samples for tHcy were immediately placed on ice, centrifuged at 4°C and 3500 rpm for 6 minutes within 1 hour and the resultant plasma supernatant was aspirated, frozen, and stored at −70°C. tHcy was determined by high performance liquid chromatography and fluorescence detection.

STATISTICAL ANALYSIS
All of the controls were compared with cases in each of four categories including all cases of retinal artery occlusions, all cases of retinal vein occlusions, cases of central retinal vein occlusions (including hemiretinal vein occlusions), and cases of branch retinal vein occlusions. An elevated tHcy level was defined as greater than or equal to 12 µmol/l. Logarithmic transformations and geometric means were used for variables showing a marked positive skew. Univariate analysis was carried out initially to determine the significance of associations between the controls and each of the four groups of patients with regard to the previously outlined variables using the Student’s t test for normally distributed continuous variables, the Mann–Whitney U test for continuous variables with a skewed distribution, and the χ² test for categorical variables. Single logistic regression models were used to examine the relation between elevated tHcy and known risk factors including hypertension and glaucoma in venous occlusive disease and hypertension and previous carotid surgery in arterial occlusive disease.

Discussion
Elevated tHcy is both an independent risk factor for atherosclerotic vascular disease and interacts with other risk factors such as smoking and hypertension to increase cardiovascular disease risk. tHcy levels are determined by both genetic and nutritional factors and possible mechanisms of action of homocysteine on vascular endothelium include promotion of platelet activation, enhanced coagulability, and smooth muscle proliferation.

Information relating abnormalities of homocysteine metabolism to retinal vascular occlusive disease are sparse and confined to two case reports and one small, uncontrolled series. Elevated tHcy has been implicated in previous studies as a possible aetiological factor in central and hemiretinal vein occlusions. However, while central retinal vein occlusions are associated with similar risk factors to retinal arterial occlusive disease, local factors such as atherosclerotic retinal arteries compressing retinal veins at arteriovenous crossings may be more important in the aetiology of branch retinal vein occlusions. This could explain the difference in risk associated with elevated tHcy between central and branch retinal vein occlusion found in this study.

While tHcy levels were significantly higher in cases of retinal artery occlusion, the small number of patients with retinal artery occlusion included in this study precludes an examination of the relation between elevated tHcy, retinal artery occlusion, and two previously determined risk factors, carotid atheroma and hypertension. Contrary to expectations, a lower proportion of cases than controls were smokers. It is more likely that smokers had ceased at the time of their retinal event, or that they were underrepresented in this elderly population because of premature mortality, than that smoking protects against retinal vascular disease.

Recent reports indicate that both nutritional and genetic factors are important determinants of elevated tHcy levels and that dietary supplementation with folic acid can reduce tHcy. The clinical inference is that measurement, treatment, and monitoring of tHcy levels may be valuable in the management of patients with retinal vascular occlusive disease not only in young or atypical patients but in those with bilateral involvement, disease in an only eye, or those in whom widespread cardiovascular disease is suspected.
Conclusions
Elevated tHcy is an independent risk factor for retinal vascular occlusive disease. In addition to an evaluation of all conventional cardiovascular risk factors, measurement of tHcy may be important in the initial investigation and management of patients with retinal vascular occlusive disease. Lowering elevated tHcy levels by administration of folic acid could improve prognosis in patients with such disease and randomised control trials to test this hypothesis are warranted.

The Research Foundation of the Royal Victoria Eye and Ear Hospital, Dublin, provided a grant for this study.

Maria Karabatzaki was supported by a student grant provided by the Health Research Board of Ireland.

Raymond Meleady was supported by an Irish Heart Foundation/Health Research Board of Ireland Unit Grant and by the European Union.
