Advancing microsurgical instrumentation into the 21st century

EDITOR,—It seems a surprising omission from the Waldocks’ recent commentary on the future of microsurgical instrumentation not to have mentioned contamination with specific reference to transmissible spongiform encephalopathies (TSE).

It is now known that prion protein is not reliably destroyed by most disinfection or sterilisation procedures, including autoclaving at a temperature as high as 138°C for an hour. Although more effective methods, such as exposure to combinations of alkali and heat, are being developed they may require instruments to be particularly durable. Also fine, and particularly, toothed instruments require thorough cleaning before sterilisation by current procedures, to avoid retention of tissue.

Although there is no clear evidence of the transmission of TSE from one patient to another by ophthalmic surgery other than through corneal transplantation, the only extant Department of Health guidelines state that any instruments used on patients with Creutzfeldt-Jakob (CJD) or suspected of this condition must be destroyed. Patients with classic sporadic CJD are predominately in their 60s and may come into contact with ophthalmologists because of cataract, glaucoma, and macular degeneration or because of visual symptoms caused by their condition.

The number of individuals in the UK who are incubating variant CJD (vCJD), believed to be the human form of bovine spongiform encephalopathy (BSE), is unknown. Prion protein has been shown to be present in the tonsils and appendices of its victims; the possibility of it being present in the eye, and particularly in the retina and optic nerve of apparently healthy individuals, must unfortunately be entertained. The Department of Health has identified neurosurgery and ophthalmology as areas of particular risk, though arguably many forms of routine surgery could pass on vCJD from one patient to another via contamination of instruments.

The only certain way to avoid the as yet unquantifiable risks of ophthalmic (or any set) surgical instruments as vectors of transmissible disease is for them to be disposable. Even then, the temptation to reuse disposable instruments for cost containment will be present. The Medical Devices Agency has already issued guidelines on devices that touch the eye, in particular contact lenses, though the full implementation of these recommendations is not possible without the eye services grinding to a halt. Nevertheless, there are situations when disposable instrumentation could be implemented—for example, eye banking, without compromising standards or indeed increasing costs, by saving on tracing and autoclaving.

We agree that surgeons, engineers, and manufacturers should engage in an active and productive debate on instrumentation for the 21st century, but this should include further initiatives to utilise new materials to facilitate disposable instruments. This dialogue may also bring about a rethink of the number of instruments on trays, the majority of which may be autoclaved time and again without being used.

EDITOR,—I thank Tullo and Taylor for their interest in our commentary and for highlighting a very important issue regarding the future of microsurgical instrumentation. Instrument manufacturers are aware of the implications of contamination, in particular from transmissible spongiform encephalopathies. We agree that there is a need for everyone associated with “high risk of transmission” surgery, such as ophthalmology, to rethink the strategies towards avoiding the risks of contamination. This needs to include a review of cleaning and sterilisation procedures as well as surgical instrument design.

As far as engineers and manufacturers of ophthalmic surgical instruments are concerned, there needs to be a complete reconsideration of instrument design. This includes a review of the materials being utilised, taking into account the need for durability to rigorous sterilisation procedures as well as cost. The assembly of the instruments must enable easy and thorough cleaning, while an evaluation of the methods by which manufacturing costs can be kept to a minimum may enable the production of affordable disposable instruments. Despite such criteria, it is important to maintain the high standards of quality which are required from instruments used in this field of surgery. This poses an interesting challenge and one which we agree requires an active and productive discussion from surgeons, eye-bank technicians, engineers, and manufacturers,

Central serous chorioretinopathy complicated by massive bilateral subretinal haemorrhage

EDITOR,—We read with interest the report by Lip et al., describing a 43 year old Asian man with central serous chorioretinopathy (CSCR) complicated by massive bilateral subretinal haemorrhage. The authors attributed the massive haemorrhage to CSCR itself. As the authors have pointed out, massive subretinal macular haemorrhage could be due to several causes, including idiopathic polypoidal choroidal vasculopathy (PCV). In their article, there is a colour fundus photograph of the left eye (Fig 3A) showing a small red nodule in the centre of fovea with surrounding subretinal haemorrhage. The lesion corresponds to the hyperfluorescent spot in the fluorescein angiogram (FA) and indocyanine green angiogram (ICGA) in the same figure (Fig 3B, C). These clinical pictures are still compatible with the diagnosis of PCV, although the presence of massive subretinal haemorrhage precludes the visualisation of other classic features of PCV. Recently, we have had the opportunity of examining a similar patient presented with massive subretinal haemorrhage in one eye, with a history of CSCR documented by FA. ICG of the other eye showed the presence of classic signs of PCV including dilated choroidal vessels with terminal polyps. As CSCR and PCV are both choroidal vascular diseases, their presence in the same eye or same patient is possible.

EDITOR,—We thank Kwok et al for their observations. Kwok et al felt that the case presented by us was compatible with a diagnosis of idiopathic polypoidal choroidal vasculopathy (PCV). We have recently described the indocyanine green angiographic (ICG) findings in a group of patients with PCV, its different modalities of treatment and follow up over a period of 6 years.

The polyps in PCV persist following recurrent haemorrhages, and only disappear following laser ablation. Ophthalmic imaging, before onset of the submacular haemorrhage, in this patient showed classic features of central serous retinopathy. There were no polypoidal lesions (including the fellow eye) seen before or after the submacular haemorrhage in our patient. The hyperfluorescent spot, shown on the fluorescein angiogram and the ICG, bears no resemblance to polypoidal lesions in PCV. In addition, a solitary lesion is not a characteristic of PCV.

We agree with Kwok et al that PCV is a cause of massive submacular haemorrhage; the coexistence of two diseases in one patient

www.bjophthalmol.com
is certainly possible. In this case, however, we feel there is no evidence that our patient had IPCV.

Retinopathy and myopia of prematurity

EDITOR,—I have some comments on the recently published article by Choi et al. dealing with long term refractive outcome and ocularometry variables in Korean children of very preterm delivery. As for the sample under study (n=65) there are certain points to state, a main point is that the 17 eyes of the ROP group were not classified from the usual preterm cohorts. The material appears highly selective; over a 6 year period, from two university clinics, only 10–11 preterm infants had been included per year. Screening limits were 1500 g birth weight and 28 weeks’ gestational age. Exclusion of a great number of pretermers appears likely, but criteria are not specified or discussed.

Eighty three per cent acquired active ROP of at least stage 3. If unselected, this is the highest figure of advanced (and of any) ROP ever reported in developed countries. Apparently 54% of all in the series had threshold ROP according to US standards and were given retinal ablation therapy by cryotechnique. Again, this represents a cryotherapy top score in ROP literature.

Seventeen eyes (out of the 125 under study) “survived” their ROP and the subsequent cryotherapy. The eventual full sample myopia frequency of 67% is very high. No account is given of visual acuity or blindness data. Myopia is a measure only on that it is very high in this case. The cryotherapy itself may be blamed for the developmental involution that myopia of prematurity, clinical signs indicated that limbal stem cell dysfunction is apparent being dragged by the macula.

In this context one may wonder why the authors preferred Reese’s classification of the early 1950s, and not its acknowledged successor regarding cicatricial ROP. It even appears as if the Reese classification was not quite followed to the letter.

For comparison, in the same issue of BJO in the US university clinic material published by Saunders et al., 143 preterm subjects were collected over 13 months and 12% acquired threshold or prethreshold ROP. To my knowledge there is no reason to assume that the Korean university clinics are not on quite such a developed level, nor that the infant susceptibility regarding ROP should markedly differ from what is known from nearby Asian metropolises. The authors further state that there are no previous longitudinal reports in the field. Depending on how “longitudinal” is defined, however, there are several studies of a rather similar type, and with emphasis on subsequent refraction and keratometry results. It is from these studies that our present knowledge is compiled.

This knowledge may be summarised as follows: In ordinary myopia the correlations between the “minor” refractive factors (corneal power, anterior chamber depth, lens thickness) all tend to lower the myopia otherwise inevitable. Independent factors:—the axial length elongation. Contra-

Reply

EDITOR,—Larkin’s letter questions the pri-

mary diagnosis in the patients listed in Tables 2 and 3 and suggests possible herpes virus ori-

nated of the disease. The question arises from our description of postoperative complica-

tions in some of our patients which include graft melting and perforation. We agree that graft melting is not a typical feature of corneal graft rejection.

We would like to clarify the clinical status of our patients. Only in two patients was the primary condition related to HSV infection. In all other grafts, in which there were no wound healing problems, the diagnoses included lime burns, keratoconjunctivitis sicca, and Stevens–Johnson syndrome without signs of herpes simplex virus keratitis. In these patients graft healing problems are related rather to the limbal stem cells and tear film deficiency than to infectious causes. In fact, it is recognised that there are sometimes difficulties in distinguishing graft rejection from infection due to chronic astigmatism defect. In our patients we made a diagnosis of rejection in association with epithelial healing problems. We cannot exclude the possibility of HSV infection of the transplanted grafts but clinical signs indicated that limbal stem cell
deficiency was the cause of the epithelial healing problem and subsequent graft melting.

MARTIN FILIPCIC

Late onset lattice dystrophy

EDITOR,—I read with great interest the article by Stewart et al on late onset corneal dystrophy with systemic amyloidosis (familial amyloidosis of the Finnish type/Meretoja syndrome) and their claim that this was the first case described in the UK. I would like to point out our case report published in the BJO in November 1999.4 We described a classic case of Meretoja syndrome in an English woman which was confirmed by genetic testing of the patient and her daughter who both demonstrated the point mutation on the gelsolin located on chromosome 9. The authors bring to our attention a second family with this disorder and rightly state that the concept of a geographically limited disorder—namely, familial amyloidosis of the Finnish type, must be treated with caution as indeed another case can occur elsewhere.

In our patient, immunocytochemistry of the corneal button removed at keratoplasty showed no labelling of the amyloid deposits with antibodies to pre-albumin, amyloid A, and amyloid P. This was in contrast with other studies where amyloid stained with antisera to serum amyloid P. Whether this represents a subtype of the condition is uncertain and it would be interesting to compare findings with Stewart et al although there is no mention of immunocytochemistry results in their paper.

Topical analgesia during retinal laser photocoagulation

EDITOR,—We read with great interest the report by Weinberger et al evaluating the analgesic effect of topical sodium diclofenac 0.1% during retinal laser photocoagulation. They found that topical sodium diclofenac 0.1% was associated with a statistically significant lower pain score compared with topical sodium chloride 0.9%, in patients receiving panretinal photocoagulation. We agree with the authors that topical sodium diclofenac 0.1% has a better analgesic effect than topical sodium chloride 0.9% in this group of patients. However, this finding may not be clinically relevant. Topical sodium chloride 0.9% does not have any significant analgesic effect. Moreover, it is a common practice that patients receive topical anaesthetic, like oxybuprocaine 4%, before the procedure or photocoagulation. It may be more meaningful to compare the analgesic effect of these two groups of agents. There is also concern about the side effects of topical diclofenac. Ocular stinging is one of them.5 This may cause patient discomfort, as well as the rating of pain score of the panretinal photocoagulation procedure. Exacerbation of asthma by topical diclofenac has been reported.6 It may not be the appropriate analgesic in laser treatment for asthmatics and in patients with obstructive airways diseases.

In summary, the role of topical diclofenac in patients receiving panretinal photocoagulation needs further evaluation.

BOOK REVIEWS

The Art of LASIK is the second edition of the well known Excimer Refractive Surgery: Practice and Principles, by Jeffrey Machat, Stephen Slade, and Louis Probst. It is an outstanding volume, which has the contributions and clinical expertise of 45 clinicians and 45 different lasers. The discussion of adjustment factors, based on altitude of the treatment centre, age of patient, and even dryness of the climate, is most interesting, as well as the discussion of LASIK, nomogram refinement from postoperative results.

Section two deals with the instrumentation involved in the LASIK procedure, including spectuums, corneal markers, tonometry, forceps and spatulas, as well as irrigation cannulas and antisedication chambers (in the rare event of a free flap). A very useful chapter devoted to in-depth discussion of various traditional microkeratomes and their compara
tive data is presented, along with excellent photographs. A specific chapter deals with the operation of the Chiron Hansatome and the “down-up” LASIK technique for production of a superior based hinge will be welcomed by both experienced and novice LASIK surgeons alike. This section also has individual chapters devoted to disposable keratomes including the FLAPmaker (used on a moni
tored basis as numerous sites worldwide, including the Center for Sight at the Queen Victoria Hospital) and the Hydroblade water-jet microkeratome.

Section three is devoted to the preoperative evaluation of the patient. This is an extremely important topic, which should be read by any one involved in the care of patients. To quote Dr Machat, “Managing patient expectations is the pivotal element to creating happy refractive patients”. Additionally, he writes “A surgeon who never has a complica
tion is one who never performs surgery”.

Candidiate selection, careful screening for pre
existing conditions and anatomical limitations, as well as contraindications for LASIK are thoroughly explored, as is the topic of LASIK as the procedure of choice of patients over the age of 40 is given, but the reality is that few refractive surgeons wish to retreat patients, and as such bilateral LASIK treatment is commonly recommended. This is unfortunate as most presbyopes wish to shed their glasses or their presbyopic

www.bjophthalmol.com

As part of the Basic Bookshelf for Eyecare Professionals series Denise Cunningham’s contribution on clinical ocular photography does exactly what it says and gives a clear, basic explanation of a range of photographic skills and techniques needed to provide an ophthalmic photography service. Aimed at anyone managing all branches of eye care, subjects covered include basic and scientific photography, ophthalmic photography, external eye, fundus photography, slit lamp photography, and fluorescein angiography with sections on darkroom techniques and photographic organisation. There are 140 pages including a comprehensive bibliography and useful index. The photographs used to illustrate various viewpoints are excellent and ingeniously devised—for example, the use a photograph of the face with drawings of the pattern of blood vessels held in front of each eye to show orientation. The quality of reproduction in the publication is somewhat lacking although this is not glossy hardback and the price reflects this. It is suggested that gaining knowledge of the interpretation of fluorescein angiography, including pattern recognition and association with disease or disorders, will make individuals’ work more stimulating and also make them more valuable to the employer.

This book does not include digital photography of any kind and neither anterior segment fluorescein angiography nor indocyanine green angiography get a mention. However, although the digital age is with us all, a good background awareness of silver based photography as related to ophthalmic photography is still very important, and this publication provides it.

ALISON FARROW

This book is a diagnostic atlas of ophthalmic ultrasound. The nine diagnostic scanning techniques and labelling formats are described with clarity in the opening chapter. The techniques described are based on those of Karl Osoining, which have been further refined by Sandra Byrne. B-scans are taken using a dedicated eye scanner with a mechanically rocked single transducer producing a sector format image. The probe is coupled to the open eye with methyl cellulose and B-scanners are much less sensitive than their more modern whole body counterparts, and often operators work on the open eye to avoid a reduction in sensitivity caused by attenuation of sound as it is transmitted through the eyelid. This atlas contains over 400 diagnostic images, three quarters of which are B-scans. This reflects a shift in stress away from the A mode technique. Each chapter concentrates on a different portion of the globe. The resolution and grey scale on images is in general poor but, despite this, the authors illustrate some retinal tears and the diagnoses given in the clear and comprehensive figure legends are correct.

The book does not cover flow mapping or spectral Doppler techniques nowadays used routinely to image blood flow. The authors generally attempt to determine blood flow in tumours by flickering of echoes as seen using A mode techniques. I found this atlas to be a clearly presented and, within the limitations mentioned above, well balanced book. I would recommend it to all those using dedicated eye scanners, and to those starting out in ophthalmic ultrasound.

MARIE RESTORI

This book will, no doubt, sell well. It has a well known editor and many prominent contributors. The book has a high quality feel to it but is let down by the very poor photographic reproduction of many of the photographs taken from preoperative videos. James Davidson (chapter 12) can produce reasonable quality stills. Why can’t the other contributors? Tables and figures, taken from lectures, may look great on screen, but look tacky when incorporated into text. There is a need for a house style since some of the chapters have attractive line drawing figures in the text. The lack of style is irritating in a subject where presentation is so obviously important. Equally irritating is the needless repetition of some figures.

I found the title a little misleading since several of the chapters, particularly those towards the end of the book, really have very little to do with clear corneal incisions. However, a small portion of the book actually deals with the incision itself. For the most part what you have is a series of descriptions of “How I do phaco” by a series of well known cataract surgeons, which is fine. Of course, there are lots of other books along the same lines and another would probably not look so attractive. What would be a catchy title for another of the same? Clear Corneal Lens Surgery? Am I being cynical?

Clear corneal cataract incisions were not practised very widely in the USA before phacoemulsification but many British and quite a few European readers will have been entertained at home with an entertaining and useful presentation through a clear corneal incision and will have been familiar with its many advantages over a corneoscleral incision. Thus, moving from a scleral tunnel to the cornea as they settled into phaco techniques was a natural and welcome step. I thought the chapter on historical background was superficial and lacking the detail which subsequent chapters contained. Expansion could have made a much more fluent introduction, which would have helped put it in better context.

Reading most of the chapters in the main part of the book I found it difficult to believe I was not reading a formalised version of the authors’ talks on their favourite method of performing cataract surgery. There was a lot of description and opinion but not very much in the way of explanation or justification. This is not the sort of book that one could dip into, and it certainly is not the sort of “cookbook” that could take a beginner through a procedure. Someone trying to identify a technique that would suit his or her personal style would have to work quite hard to get what was wanted. The information is there but there is a great deal of repetition in the process.
In summary, dear reader, if you are the sort of person who likes to read of hear about lots of nice cataract surgeons do their cataracts, then this is just the sort of book that you’ll like.

COLIN M KIRKNESS

Developments in Ophthalmology. Vol 32

It really is a misnomer to refer to Professor Behrens-Baumann as editor since he has written all but the first chapter himself. I must plead a certain personal pleasure in being asked to review this book, since I have always found Behrens-Baumann’s writing clear and to the point. He writes from a position of strength about things he understands in a way that is comprehensible to the clinician.

The approach is straightforward and logical. An overview of important ocular pathogenic fungi is provided by a mycologist. Therapeutically, there is a clear exposition of the few antifungal drugs available to us including a useful description of how these can be manufactured in drop form, which is of considerable use to those ophthalmologists working without the support of a good manufacturing pharmacy department.

There follow three large chapters or sections covering adnexal infection, keratomycosis, and fungal endophthalmitis. Histoplasmosis is treated separately and, finally, there is a chapter on laboratory experimental work which probably could be subdivided into animal models and pharmacology.

If I have any criticism it is about the very extensive listing the author provides of the clinical section. He has large tables listing fungi that have caused infection in various site—for example, lids, cornea, or endophthalmitis. It is not explicit that these lists are meant to be exhaustive but the presentation makes one assume they are. They are not. He omits a number of single case reports of infections while including others. This may just be the fault of his search engine or perhaps more likely the fault of his search engine or perhaps more likely the fact that he missed them when they were first published. It is a small point but it detracts from what otherwise would be an encyclopaedic work.

The text is, nevertheless, concise. There are only 201 pages and many of these are lists of references (381 on keratomycosis). It is highly readable and of good practical value not just for the candidate cramming for Part 3 membership but for anyone, either specialist or non-specialist, who has to manage a case of fungal infection. He gives useful information on how to improve the yield of laboratory investigation, always a difficult question. Perhaps this section could have been expanded a little. I would also like to have seen a little more on epidemiology (although this was covered) and on geographic variation which was only mentioned in passing.

These relatively minor whinges aside, this is an important text which should be on the shelf of every departmental library. The pages should be worn from constant reference. Fungal infection in the UK is rare enough that most of us have fairly limited experience in dealing with it. The easily availsable advice of an expert such as Behrens-Baumann is a godsend and is very welcome. Mr clinical director, please buy this book.

COLIN M KIRKNESS

CD ROM REVIEW

This is one of a series of CD ROMs on international health produced by the Wellcome Trust. The series was originally planned as a replacement when the trust closed its museum of tropical medicine more than 10 years ago, and has been a long time in gestation. The available software has come a long way in the past 10 years, and we have come to expect a degree of user friendliness that enables a computer illiterate such as myself to gain easy access to the material; but unfortunately this CD ROM did not come up to my expectations in this respect. It was only after some frustration and considerable help from my wife that I was able to get hold of the main menu.

The menu revealed that the material was arranged in three main scenarios: a glossary, an image library, and a tutorial. The glossary is very broad and covers a wide variety of ophthalmological terms that bear no relation to trachoma. The image library is extensive, but includes a large number of pictures of Chlamydia trachomatis at various stages of its life cycle in tissue culture; it is hard to see that these will be relevant to most users with an interest in trachoma, who are unlikely to have access to tissue culture facilities. The other unfortunate, but undeniable fact is that all images are of very poor quality when viewed on standard PCs, whether desktop or laptop. I tried both, but the images were at best of advanced cartoon standard. The tutorial was well written and well planned, but also suffered seriously from the poor quality of the images; it would be possible to learn how to diagnose or grade trachoma with images such as these.

In conclusion, given the choice, I would prefer a simple manual written on paper, which would be more easily accessible, and considerably more informative than this excessively produced CD ROM.

DAVID MABEY
