LETTERS TO THE EDITOR

Familial uveal melanoma: report on three sibling cases

EDITOR,—Uveal melanoma is the most common primary malignant intraocular tumour in adults, representing 70% of all malignant ocular tumours. The family history of some patients suggests that there could be a genetic basis. Some cases of familial uveal melanoma have been described, and they point to a dominant autosomal hereditary transmission.\(^1\)

The family uveal melanoma accounts for only 0.6% of patients with uveal melanoma. Considering the low incidence of uveal melanoma in the general population, the possibility of developing uveal melanoma in a family context is very low. Since the first description by Silcock in 1892 of the case of a mother and her two daughters affected with this illness, only 51 families had been reported until 1996.\(^2\)

Unidentified mutations on the germline line might be involved in its pathogenesis. There are several reports of simultaneous occurrence of uveal melanoma and breast cancer. Some of them are related to one of the genes already known as predisposing to breast and ovarian cancer, the BRCA2.\(^3\)

Even though there is no demonstration of an implicated gene, many studies suggest that the occurrence of family uveal melanoma is not just a coincidence.\(^4\)

Three clinical cases of histopathologically proved intraocular malignant melanoma involving first generation members of the same family (siblings) are analysed, and their evolution is reported.

CASE REPORTS

Case 1
A 40 years old male patient, with a history of ocular trauma 2 years earlier, presented with a loss of vision in the right eye, being admitted to hospital in March 2000. The earlier examination showed an ulcerated tumour in the right eye that protruded over the lower eyelid, round in shape, 1 cm diameter, pigmented and painful. He underwent a computed tomography (CT) scan of the orbit which showed an external ocular melanoma with extrascleral invasion. Studies for stratification were negative for malignancy. Given the accessibility of the tumour, a biopsy confirmed a malignant melanoma. An exenteration of the right orbit was performed in April 2000. The histopathological report was of a mixed type (spindle B and epithelioid) malignant melanoma, with perineural and perivascular scleral infiltration. A liver ultrasound performed in November 2000 showed multiple, solid, round-shaped hypoechogenic images in both hepatic lobes, compatible with secondary metastasis in the liver, confirmed by CT scan, leading to a chemotherapeutic treatment with hepatic intra-arterial cisplatin.

Because of the clear tumour progression in such a short time, a painful hepatomegaly and general deterioration and evidence of liver dysfunction, the patient could not be given and a palliative symptomatic treatment was undertaken.

Case 2
A 39 years old healthy female patient suffered a sudden loss of vision in November 1994 and a left eye retinal detachment was found at the ocular examination. The orbital ultrasound suggested a typical choroidal melanoma on the left eye. The orbital CT scan showed an intraocular tumour on the nasal side of the posterior pole of the left eye, in contact with the retina, with 10 mm thickness and probable episceral infiltration. Her left eye was enucleated on January 1995. Histopathological findings were that of a mixed cell malignant uveal melanoma, with predominance of epithelioid type, with significant scleral invasion.

In November 1997 a right breast nodule was found, measuring 2 cm in diameter. The mammography showed the right breast lump compatible with a primary breast tumour and the biopsy was positive for malignancy. It was finally removed in December 1997. The histopathological report confirmed a breast metastasis of a malignant uveal melanoma with axillary ganglion metastases.

Systemic treatment with polichemotherapy was started in February 1998, based on cisplatin, dacarbazine, and tamoxifen, five series were completed by July 1998. In August 1998 the patient suffered a right coxofemoral pain irradiated to the ipsilateral knee. Pelvic x-rays showed multiple lytic lesions in the pelvis. Bone scintigraphy (September 1998) noted hyperactive areas in the anterior arc of the third rib, pelvic bones, iliac wing, and superior third of the right femoral bone.

She was evaluated because of the risk of a local bone fracture and a surgical fixation was then implemented. Histopathological bone biopsy (November 1998) confirmed bone metastases of a melanocytic tumour, in accordance with the primary ocular melanoma. She died in December 1998 with a progressive disease.

Case 3
A 38 year old female patient, who was operated on her left breast (modified radical mastectomy) in September 1998 because of a 30 × 33 mm ductal infiltrating carcinoma (DIC), with local invasion, histological grade II, 0/6 negative axillary nodes. She then received polichemotherapy with four cycles of doxorubicin and cyclophosphamide (AC) followed by radiotherapy, completing the treatment with tamoxifen because of high positive oestrogen receptors.

In March 2000 she suffered a trauma in her right eye. An ocular ultrasound scan showed a retinal detachment and a tumoral image resembling a choroidal metastasis. The ocular computed tomography scan showed no other alterations than the apparently ocular metastasis. Liver function and enzymes were normal.

Because of the family history of ocular melanoma, enucleation of the right eye was performed in June 2000 (despite the ocular ultrasound and the CT scan oriented to a metastatic breast tumour).

The histopathology showed a mixed cell malignant uveal melanoma with predominance of epithelioid variant.

The patient is now being treated for a second breast tumour (at the remnant of the right breast).

COMMENT
The family presented includes not only three individuals affected with this unusual pathology but they are also three siblings belonging to the same generation, which is even more unusual.

All the cases corresponded to mixed uveal melanomas; in one of these cases (case 3) the patient also had a malignant breast tumour which was diagnosed 2 years before the ocular tumour; in this same case, even though the clinical findings and the imaging tests were suspicious of a choroidal metastasis, the history of two uveal melanomas in her siblings led to the enucleation of the eye, with the subsequent diagnosis of ocular melanoma; the patient is still alive but is being treated for a new breast lump.

Case 2 shows another peculiarity; the patient had been enucleated in January 1995 because of a mixed choroidal melanoma; almost 3 years later she was operated because of a probable primary breast tumour, and the mastectomy specimen showed a breast and axillary compromise of the formerly enucleated ocular melanoma. Nine months later, bone metastases of the primary choroidal melanoma were diagnosed and histologically confirmed. The patient died a few months later.

The first case (case 1) was another unusual one: at the diagnosis, the patient had an externalised ocular melanoma with extrascleral invasion allowing a preoperative diagnosis through a biopsy, even though this procedure is difficult to achieve in most of the ocular melanomas. In this patient an orbital exenteration was done owing to its extension beyond the eye itself. The histopathological report was that of a mixed melanoma (with epithelioid component). Seven months later the patient developed progressive liver metastasis with general deterioration, while under palliative care.

---

Figure 1 Genealogical family tree. UM = uveal melanoma, LC = lung cancer, BC = breast cancer, \( D_g = \) diagnostic age, \( D_e = \) dead age, \( D_g/D_e = \) diagnostic and dead age, \( y = \) years, \( I = \) first generation, \( II = \) second generation, \( III = \) third generation.
Once again this case denotes the aggressiveness of this tumour in this family.

The genealogical family tree (Fig 1) shows that the siblings’ parents developed malignant tumours: the father was diagnosed with lung cancer at the age of 59 dying a few months later and the mother had breast cancer diagnosed at the age of 49 dying at the age of 57. Also a maternal aunt was diagnosed with lung cancer at the age of 38 and died 2 years later, while another maternal aunt is still alive with breast cancer diagnosed when she was 43. The paternal family history was irrevocably without any malignancies in any of the first or second generation members.

The family tree shows, in the same generation as the affected patients, five more siblings, all of them aged less than 40 years who are currently healthy but may eventually be affected with ocular melanoma or another malignancy; are there any kind of preventive measures we can take for these patients?

Anecdotal reports of cases of ocular melanoma occurring in families with inherited susceptibility to breast cancer owing to brca2 germ line mutations have been previously reported.7 Although germ line brca2 mutations may account for a small proportion of all ocular melanoma cases, there may be additional loci contributing to family aggregation of uveal melanoma and to the family association between ocular melanoma and breast cancer.5 Based on the limited data available, an autosomal dominant mode of inheritance with incomplete penetrance has been postulated to explain the family involvement in uveal melanoma.6

In order to determine some genetic alterations that could account for this family uveal melanoma, blood samples were recently taken from different members of the family (apart from the affected patients still alive).

The family predisposition to uveal melanoma can be a component of a wider predisposition syndrome to cancer, which could explain the high number of tumours affecting these families, with multiple organs involved and the appearance at younger ages than those observed in the general population.

Because of no previous evidence of family members with uveal melanoma in the genealogical tree (Fig 1), either an environmental factor that remains undisclosed might be suspected or a new mutation may have arisen. Either way careful monitoring of the remaining siblings would be of great interest.

Hypersensitiv major keratitis after treatment with latanoprost for primary open angle glaucoma

EDITOR,—Medications used to treat glaucoma can cause side effects such as irritation, redness, foreign body sensation, and pain in the eye.3 There are reports that latanoprost has almost no serious side effects.2 We present two patients treated with latanoprost for primary open angle glaucoma who developed herpes keratitis.

CASE REPORTS

Case 1
A 68 year old female patient presented to the cornea department of the eye clinic, University of Athens, in January 1997. She was being treated for primary open angle glaucoma with latanoprost drops once daily for the past 3 months. Visual acuity in the right eye was 20/40 and in the left 20/20. The intraocular pressure of both eyes was controlled and the visual fields were normal.

On presentation, the periphery of the left eye demonstrated a dendritic ulcer (Fig 1). Immunofluorescence studies of the cornea, enzymatic hydrolysis in the cornea, where it is an esterified predrug inactivate until its metabolism we can suppose that the presence of latanoprost, ulcers, was demonstrated the presence of herpes simplex virus. Latanoprost treatment was discontinued and the patient was placed on antiviral treatment. Two weeks later the keratitis had resolved. The patient was treated again with latanoprost drops once daily in the right eye. The keratitis had recurred. The patient was treated again with latanoprost drops once daily in the right eye. There was no recurrence of the keratitis. Five months later the keratitis had resolved. The patient was treated again with latanoprost drops once daily in the right eye. There was no recurrence of the keratitis.

COMMENT

Both patients presented with herpes keratitis during latanoprost treatment. After discontinuing the latanoprost treatment, there was no recurrence of the keratitis. Latanoprost is a prostanoid analogue.4,5 It is an esterified predrug inactive until its enzymatic hydrolysis in the cornea, where it becomes a bio logically active acid.6 Owing to the biochemical disturbance in the cornea, and the keratopathy confirmed with staining, we can suppose that the presence of latanoprost predisposes the appearance of herpes keratitis.

More cases must be studied before we can reach more specific conclusions.

Optic neuropathy and cerebellar ataxia associated with a rare missense variation (A14510G) of mitochondrial DNA

EDITOR—Mitochondrial diseases manifest a variety of syndromic signs. Skeletal muscle, central nervous system, heart, eye, ear, liver, kidney, pancreas, bone marrow, and colon are the most frequent organs in mitochondrial diseases. The mitochondrial DNA (mtDNA) is responsible for the mitochondrial diseases through molecular defect of oxidative phosphorylation enzymes in conjunction with the nuclear genome.1 Optic neuropathy and cerebellar ataxia are a frequent association in mitochondrial diseases. We report a sporadic case of bilateral optic neuropathy, cerebellar ataxia, and peripheral neuropathy associated with a rare missense variation at A14510 which replaced Val by Ala in the ND 6 coding sequence of mtDNA.

CASE REPORT
A 52 year old Japanese man first noted writing disturbance, tremor of hands, and mild gait disturbance at the age of 49 years. The patient had a 30 year history of drinking (daily alcohol consumption 125 g) and smoking (daily 20 cigarettes). Physical examination revealed a series of neurological signs including cerebellar ataxia and peripheral neuropathy. The gait was broad based and ataxic. There was mild ataxia of the lower extremities on heel to knee test. Deep tendon reflexes were hyperactive with normal plantar responses. Peripheral nerve conduction velocity studies revealed sensory polyneuropathy in the upper and lower limbs. Muscular strength and volume of the limbs were normal. Magnetic resonance imaging showed cerebellar atrophy with dilatation of the fourth ventricle (Fig 1). The cerebrospinal fluid was normal without any inflammatory signs. Peripheral blood examination showed mild macrocytic anaemia. The serum levels of vitamin B1, vitamin B12, and folate acid were within the normal range. Red blood cell folate level was also normal. The patient had been suffering from progressive loss of central vision in both eyes since 51 years of age. At presentation, best corrected visual acuity was 0.1 in the right eye and 0.08 in the left. Pupils were round, isocoric, and sluggish to light. There was no blepharoptosis. Ocular motility was normal. Anterior segments and media were clear. Funduscopy disclosed dilatation of small retinal vessels neighbouring the optic nerve head in both eyes. Retinal nerve heads were not hypopigmented but slightly atrophic with temporal pallor. Static and kinetic visual field testing showed central scotomas. Farnsworth’s panel D-15 test showed red-green colour vision defects. Full field scotopic electroretinograms and visual evoked cortical potentials were normal. The patient was the fourth of five siblings of non-consanguineous parents. Because of the alcoholism, he was divorced and lived alone. Family members were not accessible, but according to his statement, there was no relative having similar disease. Although the clinical signs in this patient were not consistent with the effects of chronic alcoholism and tobacco abuse alone, we could not dismiss the diagnosis of a mitochondrial disease subtype because of the bilateral optic neuropathy accompanied by cerebellar ataxia. Peripheral blood was obtained after informed consent and examined for common pathogenic mtDNA point mutations by polymerase chain reaction (PCR) restriction methods described elsewhere.1 The nucleotide sequences of sense and antisense strands of ND1, ND4, and ND6 genes of mtDNA from the patient were evaluated by autosequence methods in the patient, no major pathological mutation was found by PCR restriction detection at np 3243 for mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episodes (MELAS), 3460 for Leber’s hereditary optic neuropathy (LHON), 13447 for myoclonic epilepsy and ragged red fibres (MERRF), 8993 for neurogenic weakness, ataxia, and retinitis pigmentosa, 11778 for LHON, or 14484 for LHON. There was no known mutation in ND1, ND4, or ND6 gene of mtDNA by nucleotide sequencing. Instead, nucleotide sequencing and Alu I restriction detection confirmed a homoplasmic missense mutation at np 11778 (A14510G) that replaced Val by Ala in the ND 6 gene of mtDNA (Fig 2). The DNA samples reserved by us were examined for the relevant mtDNA mutation. The A14510G mutation was not detected in 468 Japanese individuals, including 39 LHON patients with 11778 mutation, 24 healthy carriers with 11778 mutation, one LHON patient with 3460 mutation, one LHON patient with 14484 mutation, 78 patients with aetiology undefined bilateral optic neuropathy, 239 patients with spinocerebellar ataxias who did not carry any abnormal nucleotide sequences in the genes of spinocerebellar ataxia type 1, 2, 3, 5, 6, 7, or 8, and 86 unrelated healthy individuals. Thus, grouped with previous data in other populations, the frequency of A14510G is estimated to be two in 1413, or approximately one in 700. Noticeably, this frequency is remarkably rare compared with commonly found mtDNA polymorphisms that are innocent or not pathogenic. Although clinical information from the Australian with A14510G is not available, it is possible to assume that the mtDNA plays a part in the aetiology of a syndromic clinical disorder. We could not confirm maternal inheritance or heteroplasmy of the A14510G mutation in our family. According to the statements from the patient, the family members had normal vision but clinical and molecular genetic assessments in them may give significant information for the genotype–phenotype correlation of the A14510G mutation.

Mutational effect of A14510G is unknown. Two of the primary mtDNA mutations, G14355A (Ala72Val) for LHON plus dystonia and T14484C (Met64Val) for LHON, have been verified near A14510G (Val55Ala) in the ND6 gene.1 Another missense mutation (A14499G, Leu60Ser) has recently been found in the same gene in two LHON families, suggesting that the ND6 gene is a hot spot for LHON mutations.2 The amino acid sequence relevant to A14510G (VFLLYLGGMMVFQGTYYTA; letters in bold are replaced by the mutations) is highly conserved in mammalia including human, bovine, and mouse, but not by conserved in Xenopus, sea urchin, or drosophila. This region is a part of hydrophobic transmembrane helices of the ND enzyme. Mutations in the ND6 gene may disturb the enzymatic stability of NADH CoQ reductase.

Optic neuropathy is the predominant sign of LHON and may also be developed in patients with other mitochondrial disorders such as chronic progressive external ophthalmoplegia, MELAS, and MERRF, occasionally associated with a rare missense variation (A14510G) of mitochondrial DNA.
characterized by insidious, chronic progressive optic nerve disease.1 Our patient developed a late onset, insidious bilateral optic neuropathy with mildly atrophic optic nerve heads and tortuous retinal vessels, being compatible with features of LHON.2 Cerebellar ataxia and/or cerebellar atrophy are caused by mutations of mtDNA—for example, large scale deletions or tRNA mutations.3 An extensive review of the literature demonstrates a variety of neurological abnormalities in LHON patients, including cerebellar ataxia and peripheral nerve disorders.4 Our patient had cerebellar ataxia and sensory polyneuropathy, with evidence of cerebellar atrophy on magnetic resonance imaging. Similar neurological complications were rarely found in a LHON family with G11778A mutation.5

Although epiphenic factors have been considered for the disease expression and visual outcome of LHON patients in association with mtDNA mutations, it has yet to be proved. A retrospective analysis of LHON sibships has failed to demonstrate a significant deleterious association between tobacco or alcohol consumption and vision loss among individuals at risk with the major mtDNA mutations.6 In the present clinical isolate, it remains unknown whether the malnourishment condition provided a potential risk factor in the clinical manifestation associated with the underlying mtDNA defect. The A14510G mutation of mtDNA is expected to be found in other independent patients especially with unknown optic neuropathy and cerebellar ataxia.

No proprietary interest.

Comment

In our series, HLA-A24 is found in 67% of the patients, compared with 14% in the Spanish control population (p > 0.05, Fisher test). No other HLA class II allae shows a remarkable deviation from the control population. Regarding HLA class II alleles, HLA-DR14 (a HLA-DR6 subtype) is found in two of our patients, whereas it appears in eight of our control individuals (67% vs 4%, p=0.006; OR 48.2 [95% CI 5.5–3.5]). We conclude that HLA DR6 association previously reported in other populations. The frequency of other HLA class II alleles is also increased in the diseased group when compared with the control group, although statistical significance is not reached: HLA-DQ5 (100% vs 40%, p > 0.05, Fisher test) and HLA-DQ52 (100% vs 56%, p > 0.05).

When aetiological fraction (z) is considered, HLA-DR14 and HLA-DQ5 show the highest value (s0.71), followed by HLA-DR14 (z0.74) and HLA-A24 (z0.71).

These data point to HLA class II antigens rather than HLA class I as the main TINU susceptibility markers. It may be worth recalling that HLA class II molecules are expressed in renal epithelial cells or in the uvea when inflamed. Thus, genetically predisposed individuals (that is, HLA-DR14) would be more prone to producing the lesions observed in the TINU syndrome upon activation of the immune system.

We are aware of the limited value of the statistical analysis carried out given the small number of patients studied, but this is inherent to the pathology itself, since scarcely 50 TINU patients have been described worldwide since its first description in 1975. We thus would use HLA phenotyping in future patients to assess the role of these HLA class II antigens in TINU susceptibility.

We are grateful to Dr A Annaz-Villena (Immunología Hospital “12 de Octubre”, Madrid) for HLA typing of patients.

An 80 year old white woman presented complaining of sudden deterioration in vision in her left eye. Her ocular history was remarkable for atrophic AMD. Visual acuity was 20/200 in her left eye. Her ocular history was remarkable for atrophic AMD. Visual acuity was 20/200 in her left eye.

CASE REPORT

An 80 year old white woman presented complaining of sudden deterioration in vision in her left eye. Her ocular history was remarkable for atrophic AMD. Visual acuity was measured at 6/6 in the right eye and counting fingers in the left eye. On fundus examination of the right eye diffuse soft confluent drusen, some calcified, and geographic atrophy (GA) were detected (Fig 1A). In the left, the most striking feature was the presence of marked and diffuse cystoid macular oedema (CMO), and a serosanguineous pigment epithelial detachment (PED) associated with large amounts of hard exudates (Fig 1B). Soft and calcified drusen and GA were also present. Fluorescein angiography (FA) disclosed diffuse pooling of dye in the macula in the left eye, and an area of hyperfluorescence corresponding to the PED (Fig 2A). Window defects corresponding to areas of atrophy were detected in both eyes. On indocyanine green angiography (ICG) a choroidal vascular network of polypoidal structures was observed in the left eye (Fig 2B, C).

After informed consent was obtained, focal laser photocoagulation using an argon laser was applied to polypoidal vessels. The parameters used were a laser power of 200 mW, an exposure time of 0.2 seconds, and a spot size of 200 µm. This resulted in resolution of the CMO and PED (Fig 2D) on FA, closure of the choroidal vascular network on ICG (Fig 2B, E), and on a subjective improvement in vision 2 weeks following laser treatment.

COMMENT

IPCV is characterised by the presence of recurrent serosanguineous PEDs and neurosensory retinal detachments (NSRD). The vascular abnormality underlying the disorder appears to be in the inner choroid. Dilated networks of vessels terminating in aneurysmal dilatations or “polyps” can be observed on ICG angiography. Polypoidal lesions may arise from the peripapillary region, macula, or peripheral areas. Histopathological evaluation of a case of IPCV showed extensive

Figure 1 Fundus examination of both eyes disclosed soft confluent and calcified drusen and areas of geographic atrophy (A and B). In the left eye, a neurosensory detachment of the macula and a serosanguineous pigment epithelial detachment surrounded by extensive hard exudation were also present (B, arrowheads).

Figure 2 On fluorescein angiography pooling of dye at the macula was observed in late phases (A). An area of bright hyperfluorescence with late staining, corresponding to the serosanguineous pigment epithelial detachment, was also present (A). On indocyanine green angiography, a network of dilated channels terminating in aneurysmal dilations was observed in early frames of the angrogram (B), and leakage from this vascular network was detected in late frames (C). Laser photocoagulation was applied to cover the vascular network shown in B (inset). Following laser treatment, resorption of the neurosensory detachment of the macula and pigment epithelial detachment was noted on fundus examination and on fluorescein angiography (D). Closure of the polypoidal vessels was confirmed by indocyanine green angiography (E).
fibrovascular proliferation in the subretinal space and within Bruch’s membrane, and a marked lymphocytic infiltration with both B and T cells. Although laser photocoagulation appears to be very effective in preserving visual acuity in patients with IPCV, spontaneous resolution of PEDs and NSRDs can also occur.

The patient described in this report had evidence of atrophic AMD. However, the diagnosis of IPCV was suspected by the presence of a marked NSRD, extensive and diffuse hard exudates, and a serousanginous PED. Since it was not clear whether GA was involving the fovea in the left eye, laser treatment was applied in an attempt to achieve resolution of subretinal fluid and hard exudates and in the hope that an associated visual improvement will occur. Rapid resolution of all subretinal fluid was noted and, more spectacularly, resolution of the serosanginous PED, distantly located from the treated area, was also observed 2 weeks after laser treatment. Although no objective improvement in visual acuity was measured, the patient perceived a gain in vision after the treatment. Although probably rare, IPCV can occur in patients with atrophic AMD. A high index of suspicion may be required to establish the diagnosis in these cases.

Spontaneous orbital haemorrhage following cardiac angioplasty

EDITOR—Orbital haemorrhage occurs most commonly following trauma, retrobulbar injection, or orbital surgery. Spontaneous orbital haemorrhage is a rare condition usually associated with vascular anomalies, lymphangiomas, or systemic haematological disorders. Rarely, it has been reported in pregnant females being treated with subcutaneous heparin. In this case report, we describe a woman who developed a spontaneous orbital haemorrhage in the perioperative period following cardiac angioplasty.

CASE REPORT
A 48 year old woman awoke with blurred vision and diplopia in her left eye 1 day after percutaneous coronary angioplasty for coronary stenosis. Before angioplasty she received RecPro (abciximab), a glycoprotein GP IIb/IIIa antagonist. There was no ocular history of note but she was known to have had treatment for hypertension and hypercholesterolaemia. Her medication includes angiotensin included subcutaneous heparin, aspirin, and clopidogrel—a P2 receptor antagonist. On examination, her best corrected visual acuity was 6/9 left 6/6 right. There was no evidence of a relative afferent pupillary defect. There was no desaturation on field examination with a red target in either eye. The left eye was proptosed by 4 mm (Fig 1). There was evidence of limitation in elevation and dextroversion giving vertical and horizontal diplopia in those positions of gaze. Anterior segment was entirely normal but for slight chemosis (Fig 1) and the posterior segment examination including fundoscopy did not reveal any abnormality. An MRI scan of the orbit (Fig 2) revealed an intraorbital extracranial acute haemorrhage measuring 1.7 cm and lying superior and lateral to the superior rectus muscle and displacing it. There was no evidence of optic nerve compression. She had a normal platelet count and clotting screen. Her haematologist was not concerned about bleeding tendencies. She was managed conservatively and made a complete recovery with 6/6 vision in each eye at 4 months after haemorrhage.

COMMENT
This case represents a rare case of spontaneous orbital haemorrhage. Most cases of reported spontaneous orbital haemorrhage appear to have a cause to which the haemorrhage could be referred to like venous anomalies of the orbit such as lymphangiomas, haemangiomas or carotid cavernous fistulas. Other predisposing factors include blood dyscrasias such as Von Willebrand’s disease or haemophilia. Heparin has been implicated in two cases of pregnant women treated with subcutaneous heparin and hypertension, and Valsalva manoeuvres have also been implicated as possible causes. In this particular case, it is not clear what the predisposing factor may be. This woman was receiving ReoPro (abciximab) a recent glycoprotein GP IIb/IIIa antagonist, which has marked antithrombotic effects. Further, as well as aspirin and subcutaneous heparin, she was also receiving clopidogrel—a P2 receptor antagonist, which inhibits platelet aggregation. We might speculate that one of these newer agents or combinations of these agents may have been responsible. Against this evidence, however, was the finding of a normal platelet count and clotting screen. In this particular case, the patient made a complete recovery probably as a result of venous bleed. However, many cases of spontaneous orbital haemorrhage reported have required surgical intervention with variable prognoses. Ophthalmologists need to be vigilant and carefully monitor these rare cases.
