Acute angle closure glaucoma following the use of intranasal cocaine during dacryocystorhinostomy

Many thousands of dacryocystorhinostomies (DCRs) are performed by ophthalmologists routinely without problems. Postoperative pain and nausea may wrongly be attributed to wound pain and post-anaesthetic nausea. Medical and nursing staff need to be aware of the potential for intranasal cocaine to precipitate acute angle closure glaucoma (AACG). We report two cases of AACG following the use of intranasal cocaine and subcutaneous lignocaine (lidocaine) with adrenaline during DCR surgery. We believe this to be the second report of such cases.

Case report

Two women, a 67 year old and a 75 year old, developed right sided AACG immediately after ipsilateral DCR surgery. Both patients were treated successfully for AACG. Cocaine is a known mydriatic and can induce angle closure glaucoma in predisposed individuals. Adrenaline in the local anaesthetic solution and intravenous atropine sometimes used during general anaesthesia are also known mydriatics.

We performed right sided external DCR surgery under general anaesthesia on both females. Regional preparation included a cocaine nasal pack (5% solution) and infiltration with lignocaine and adrenaline 1:200 000 at the proposed incision site subcutaneously. Preoperative intraocular pressures were within normal limits and there was no history of previous attacks of AACG or subacute angle closure glaucoma in either patient.

Overnight, both developed right eye pain and nausea and each was given analgesia and an antiemetic. Medical staff were not called to review the patients. The following morning, dressings were removed and a diagnosis of right sided AACG was made. Each patient had corneal oedema, a mid-dilated and non-reactive pupil, anterior chamber flare, and 360 degrees of angle closure on gonioscopy.

In the 67 year old, the intraocular pressure measured 18 mm Hg in the right eye. This may be explained by spontaneous termination of the attack as a result of ciliary body ischaemia and suppression of aqueous secretion secondary to a high intraocular pressure overnight. In the left eye the intraocular pressure was 15 mm Hg and gonioscopy showed 270 degrees of grade 1 open angle, and 90 degrees of complete angle closure. Uneventful bilateral YAG iridotomy was performed.

In the 75 year old, the pressure was recorded as 57 mm Hg in the right eye and only dropped to 39 after two doses of intravenous mannitol. Gonioscopy of the left eye revealed a 360 degree closable angle, grade 0-1. Uneventful bilateral YAG iridotomy was performed. The corneal oedema resolved over the following week in both patients and visual field testing revealed no glaucomatous defect. Both patients require ongoing antiglaucoma therapy.

Comment

Cocaine is the only local anaesthetic to block noradrenaline reuptake at the presynaptic adrenergic receptors. This single agent provides anaesthesia and haemostasis, making the use of cocaine desirable in lacrimal drainage surgery. Its use in DCR surgery was first described by Dupuy-Dutemps and Bourgener in 1922. We have routinely used cocaine for our DCR surgery, and emphasise the need to remain cognisant of its possible local and systemic side effects.

Cocaine is well absorbed from mucosal surfaces, reaching plasma levels similar to those achieved with intravenous administration. In adults, 50–95 mg is a psychotomimetic dose. The maximum allowable dose is 3 mg/kg; 1 g or 10 ml of a 10% solution represents a fatal dose for an adult. Usually, 80–200 mg of cocaine is administered intranasally in DCR surgery. Systemic cocaine toxicity has been reported in patients undergoing DCR surgery under general anaesthesia.

AACG was described in the early 20th century with the use of cocaine as a corneal mydriatic. More recently, a case of AACG associated with ipsilateral intranasal cocaine abuse was reported. In 1999, Hari et al described a single case of AACG following the use of cocaine in DCR surgery. Our two case reports strongly suggest that the use of intranasal cocaine to aid DCR surgery may precipitate AACG.

It is highly probable that the mydriasis which precipitated the attack of AACG was caused by the intranasal cocaine rather than the low concentration of subcutaneous adrenaline (1:200 000). There are two possible mechanisms of cocaine entry into the eye during DCR. Inadvertent transfer of cocaine from the surgeon’s glove to the patient’s conjunctival sac is possible if fresh gloves are not used between cocaine nasal packing and the infiltration of local anaesthetic. Alternatively, residual cocaine in the nasal cavity has direct access to the conjunctival sac after the lacrimal sac anastomosis in the DCR procedure.

Other potential causes of AACG include the mydriatic effect of the adrenaline in the lignocaine 1%, 1:200 000 adrenaline, and atropine given intravenously during general anaesthesia.

At this concentration, subcutaneously administered adrenaline is unlikely to have precipitated the acute angle closure glaucoma. Atropine was not used during anaesthesia in either patient.

Given the apparent rarity of this proposed event, we cannot definitively conclude that lacrimal surgeons should change their approach to patients undergoing DCR surgery. However, it is important to remain cognisant of this potential complication and educate both nursing staff and medical trainees in ophthalmology and otolaryngology as to this potential complication. In addition, it would be reasonable to pad only the wound and not occlude the eye, which may have allowed the origin of the pain in our cases to be more readily identified. Postoperative pain and nausea following DCR surgery should not be automatically attributed to wound pain and post-anaesthetic nausea: A case of AACG needs to be excluded. It may be prudent to assess routinely anterior chamber depth in high risk eyes before DCR surgery. If there is any suspicion of an eye anatomically predisposed to AACG both nursing and medical staff should be made aware of the potential complication. A prophylactic peripheral iridectomy may be indicated.

Presumed hypersensitivity to minocycline and conjunctival infiltration

Minocycline is a widely prescribed systemic antibiotic for acne. Its mechanism of action is complex and not only antimicrobial in nature. Other properties of minocycline include decreased chemotaxis of polymorphonuclear leukocytes, a modification of the complement pathways, an inhibition of the polymorphonuclear leucocyte chemotactic factor, and inhibition of lipase production in Propionibacterium acnes. In ophthalmology, minocycline is used for the treatment of rosacea. Although commonly considered to be a safe drug, there have been an increasing number of reports regarding systemic adverse reactions to minocycline during the past few years. Adverse effects to minocycline range from minor allergic reactions to death. The only ocular side effects reported to date have been cases of presumed minocycline induced scleral pigmentation. We report a case of conjunctival infiltrates, asthma exacerbation, and hypereosinophilia associated with the concurrent use of minocycline.

Case report

A 28 year old woman received oral minocycline 100 mg once daily, for 29 days for the treatment of acne, without any other topical or systemic medication. She had a history of multiple allergies and asthma since early childhood, but no ocular history. During the first days of treatment, she developed asthenia, a mild fever of 38°C, and severe asthma. She was hospitalised. Thirty days after the beginning of minocycline treatment, she reported redness and burning of both eyes. Visual acuity was 20/20 in each eye. Several slightly elevated intraconjunctival nodules were seen in both eyes at the 12 o’clock position, with injection of the superficial and deep episcleral vessels (Fig 1). The tear film and the corneal epithelium were normal. There was no inflammation of the anterior chamber or of the posterior segment. Laboratory tests showed a severe eosinophilia: 2.12 × 10^9/l and 4.0 × 10^9/l, at 15 and 30 days, respectively, after the onset of oral minocycline. Treatment of the patient’s asthma included systemic prednisone initiated at 0.5 mg/kg/day. Cessation of minocycline led to rapid remission of asthma. Despite no topical treatment for her ocular findings, the conjunctival infiltration disappeared, and the ocular symptoms resolved. Laboratory tests showed a rapid decrease of the eosinophilia: 1.06 × 10^9/l and 0.7 × 10^9/l at 3 and 9 days, respectively, after cessation of minocycline.

A conjunctival biopsy was performed 39 days after the onset of minocycline treatment. Histopathology showed no modifications of the conjunctival epithelium, but oedema of the stroma. Vessels were surrounded with mononuclear lymphocytes and eosinophils. May-Grunwald-Giemsa staining confirmed eosinophilic polynuclear cells. Such inflammatory aggregates were also seen between vessels but not inside the vessel lumens (Fig 2).

Comment

Reports of adverse effects of minocycline include both hypersensitivity reactions and autoimmune disorders. Hypersensitivity reactions usually occur within a few weeks after the onset of treatment and may lead to exfoliative dermatitis, eosinophilic pneumopathy, pericarditis, lymphadenopathy, pseudoinfections, and blood eosinophilia (that is > 0.6 × 10^9/l). Autoimmune disorders usually present after exposure to minocycline for 1 year or more and include autoimmune hepatitis, lupus, and vasculitis. Pigmentations of the skin, fingernails, bones, and teeth have also been described in relation to the use of minocycline. Seven cases of scleral pigmentation have been reported.

Exacerbation of asthma and eosinophilia similar to our observation have been previously reported. The definite temporal association with conjunctival infiltration strongly suggested that minocycline therapy was the causative agent in our case. The patient’s clinical findings did not show any abnormality of the superficial corneal epithelium near the limbus or any tear film abnormalities, as observed in a superior limbic keratoconjunctivitis-type reaction. Neither the transient nature of asthma and eosinophilia, nor the biopsy specimen was suggestive of Churg-Strauss disease in our patient. Different ocular manifestations, such as splinter haemorrhages and arterial emboli have been reported in the hyper eosinophilic syndrome (eosinophil counts greater than 1.5 × 10^9/l), linked to chorioretinal thromboembolic disease. No thromboembolic manifestations were observed in the conjunctiva of our patient.

To our knowledge, our observation is the first report of a drug induced eosinophilic conjunctival infiltration.

Importance of molecular testing in dominant optic atrophy

Juvenile onset dominant optic atrophy (DOA) is the most common inherited optic atrophy with a variable prevalence of between 1 in 10 000 (Denmark) and 1 in 50 000.1,2 The majority of cases have been shown to have mutations in the OPA1 gene on chromosome 3.3 Reduced visual acuity of insidious onset, temporal pallor of the optic disc, centrocaecal scotoma, and generalised dyschromatopsia are the key clinical features.4 Recent studies, however, have shown that penetrance within families is much lower than first realised and the assignment of status using clinical criteria alone can result in misdiagnosis.5 This is well illustrated by the following family.

Fifteen family members were asked about perceived visual difficulties before measurement of visual acuity, colour vision (City University Test), and visual field analysis (Humphry 24-2). Fundal examination and photography were performed. Blood was taken for screening of the OPA1 coding region using single stranded polymorphism analysis (SSCP) and automated DNA sequencing as previously described.6

Seven family members were diagnosed as having optic atrophy from clinical tests alone (Fig 1). Where visual disability was recognised the age of onset ranged from 5.5 to 20 years (Table 1). Eight family members were classified as affected from molecular testing. All individuals exhibited an abnormal banding pattern on SSCP analysis of exon 27 (Fig 2). Sequencing revealed a four base pair deletion of TTAG at the start of exon 27 (nt2708 delTTAG). This deletion has been described previously and causes a frameshift resulting in two amino acid substitutions (Val903Gly, Arg904Asp) and a premature stop codon.

Dominant optic atrophy may be the result of mutations in genes other than OPA1.7 However, where DNA linkage analysis or mutation screening implicates the OPA1 gene we feel that all family members should be offered molecular testing. In DOA it is well recognised that the clinical manifestation of the same mutation within a family can be very variable.8 This is well illustrated in Table 1. Genetic screening is the only reliable way of identifying individuals at risk of passing on defective genes to their offspring. In this family the combination of SSCP and DNA sequencing resulted in an alteration of the status of individual II:7 from unaffected to affected. If clinical tests alone had been relied upon, this individual would have most likely received incorrect genetic advice.

Table 1 Data showing the clinical results of visual acuity, colour vision, field analysis, and funduscopy from selected family members. The colour vision was tested for monocular and binocular tritan (blue-yellow), deutan (green), and protan (red) defects which were scored out of 10 plates

Y = Yes; N = No. *Classified as affected from clinical tests alone.
tions revealed a raised plasma viscosity (3.28 s) in a patient suffering from multiple myeloma. Investigation for breathlessness led to the diagnosis of an acute pulmonary embolism. The patient was diagnosed with multiple myeloma and treated with thalidomide and dexamethasone. The patient's visual acuity deteriorated to 6/9 as the crystalline keratopathy worsened.

Comment

Crystalline keratopathy occurs only rarely in association with multiple myeloma and monoclonal gammopathies. With the exception of Waldenstrom's macroglobulinemia, the crystals are composed of IgG light chains (usually κ but occasionally λ). The crystals may be deposited in the epithelium, as in the case we present, where they have been reported to lie both between and within the epithelial cells, and also within the cells of the corneal stroma, conjunctiva, and lens.

It is not known why crystallisation occurs so infrequently in these conditions or why clinical appearances are so diverse, but factors including the structure, chemical properties and concentration of the paraprotein or its metabolites, and the local tissue environment are likely determinants. The effect of concentration cannot be disputed as the crystals tend to disappear as the paraprotein concentrations fall; however, the rarity of these corneal crystalline deposits suggests that the chemical and tertiary structures of the proteins or their metabolites is critically important.

Although it is reported that myeloma associated crystalline keratopathy can disappear in response to chemotherapy and plasma exchange there are no previous reports of resolution following the use of thalidomide in refractory disease.

The mechanisms of action of thalidomide are complex and poorly defined but include immunomodulatory and anti-inflammatory effects, the modulation of TNFα, T cell proliferation, increased production of IL2 and IFN-γ and modulation of WBC migration and chemotaxis. The drug also has important anti-angiogenic effects which may be related to modulation of TNFα or a direct inhibitory effect upon angioproliferation. Thalidomide is also sedative and hypnotic and its use for these latter effects gained infamy in the 1960s.

A 64 year old man presented to the ophthalmic service complaining of glare at night which had worsened over a 12 month period. He was found to have a pancorneal epithelial crystalline keratopathy with normal Snellen acuity (6/5 both eyes) and an otherwise unremarkable ocular examination (anterior chamber, lens, vitreous, and fundus). The crystalline keratopathy stretched from limbus to limbus with normal Snellen acuity, and reduced glare for several weeks before deterioration occurred once more. Over the next 2 years the epithelium was debried alternately from one eye and then the other every 2–3 months and visual acuity was maintained at 6/6 to 6/9 Snellen.

Two months after completing CIDEK the myeloma relapsed (paraprotein 38.7 g/l) and despite the use of weekly cyclophosphamide his renal function rapidly deteriorated (creatinine 714 μmol/l). The thalidomide was re-introduced in combination with dexamethasone (paraprotein 52.8 g/l) and no longer responding to treatment. Initially he was started upon 50 mg daily; however, a peripheral neuropathy developed when the dose was increased to 100 mg daily and treatment was stopped for 3 weeks. The thalidomide was re-introduced in combination with dexamethasone, 4 days on 4 days off. The dexamethasone was slowly tailed off and the thalidomide reduced to 50 mg on alternate days and latterly to 50 mg twice weekly. Within 7 months of starting the thalidomide, the paraprotein had completely disappeared and the crystalline keratopathy had resolved (Fig 1C, D). Visual acuity at this time was 6/9 right eye and 6/18 left eye, due now in large part to the presence of early posterior subcapsular lens opacity.

Figure 1 Slit lamp photographs of the left cornea. (A) Before thalidomide, low power. (B) Before thalidomide, high power. (C) After thalidomide, low power (pupil dilated). (D) After thalidomide, high power (pupil dilated).
like our patient, achieving complete remis-
sion. Although the anti-angiogenic effects of
thalidomide are generally considered a key
factor in the efficacy of the drug in multiple
myeloma, the poor response of extramedul-
lar plasmacytomas and the lack of correla-
tion between bone marrow microriceu-
density and clinical response suggest that
other actions of the drug may also be
important.7

In summary, we report a case of a refractory
multiple myeloma with associated corneal
keratopathy in which resolution of the
paraproteinaemia and corneal crystalline
deposits occurred concurrently and following
the initiation of thalidomide therapy. The
report provides further support for the use of
thalidomide in refractory multiple myeloma.

Iris coloboma and a microdeletion of chromosome 22: del(22)(q11.22)

A 22q11 microdeletion is described in a girl
with ocular coloboma associated with velo-
cardio-facial syndrome (VCFS).

Microdeletion syndromes are a heterogene-
uous group of disorders caused by deletion of
specific regions of chromosomal DNA that
are not visible using standard chromosome
analysis.3 Microscopic chromosome deletions
are being recognised increasingly as a cause of
genital abnormality and clinical genetic
syndromes. Laboratory confirmation of these
conditions requires specialist molecular test-
ing that must be requested on the basis of
clinical suspicion. Del(22)(q11.22) microdele-
tion is among the most common of the micro-
deletion syndromes and is characterised by
cardiac malformations (particularly outflow
tract), craniofacial features, cleft palate, thymic hypoplasia, and hypoparathyroidism.

The severity of the condition can be very vari-
able and is now recognised as the basis of sev-
eral independently described syndromes: Di-
George syndrome (DGS), conotruncal face
anomaly syndrome, and velo-cardio-facial
syndrome (Shprintzen syndrome).7 The “velo” in
VCFS refers to the palatal abnormalities such as
cleft palate that are sometimes present. The
characteristic facial appearance of del(22)(q11.22) is a prominent nose, broad
nasal root, narrow palpebral fissures, and
retrognathia. Recognised ocular features in
clude retinal vascular tortuosity, small optic
nerves, and narrow palpebral fissures.8 An iris
coloboma has been described in one case of
VCFS and coloboma was listed as a rare
feature in a series of cases of DGS.9

Case report

As part of a population based study of children with congenital anophthalmos, clini-
cal microphthalmos, or iris coloboma (with or
without fundus coloboma), we identified a
teenage girl with bilateral iris coloboma, right
fundus coloboma, left cataract, and clinical
microphthalmos (Fig 1). On further examina-
tion she was found to have upslanting palpe-
bral fissures, prominent nose, small mouth,
dental crowding, unilateral deafness, arachno-
dactyly, second and third toe syndactyly (Fig
1). Intraocular pressure was elevated in the
right eye. The left eye was normotensive.

Figure 1 Bilateral iris coloboma with clinical microphthalmos in a girl with velo-cardio-facial syndrome. Note the upslanting and narrow palpebral fissures, wide nasal root and bridge, with prominent nose, and small mouth.

Figure 2 Second and third toe syndactyly in a girl with velo-cardio-facial syndrome and del(22)(q11.22).

Anamnestic membrane transplantation for necrotising conjunctival ulceration following subconjunctival atropine injection

Conjunctival necrosis has been previously
reported after subconjunctival injection of
several antimicrobial agents and corticosteroids.40 Atropine is used widely as a form
of eyedrops for mydriasis, cycloplegia, and
pain and inflammation control. We
A 30 year old male patient visited our clinic because of severe pain and redness in his left eye for a day. He had recently been diagnosed with uveitis associated with circular posterior synechiae. Upon consultation at our institute, he was found to have marked conjunctival injection of 0.4 ml of atropine (10 mg/ml atropine sulphate, powder dissolved in saline, Mallinkrodt, St Louis, MO, USA) to lyse the posterior synechiae. Upon consultation at our institute, he was found to have marked conjunctival injection and chemosis all around the limbus. Three days after the atropine injection, large areas of necrosis developed around the whole limbus (Fig 1). White necrotic materials were noted on the underlying sclera and episclera. The underlying sclera in the inferotemporal bulbar conjunctiva showed a considerable area of melting (2 × 3 mm).

We decided to manage the defect by amniotic membrane transplantation to the sclera because of the large extent of the defect and the scleral involvement. Debridement of the necrotic conjunctiva and episclera was done and the defect was covered with an amniotic membrane graft, which was obtained from women undergoing elective caesarean section and preserved at −70°C. The amniotic membrane was placed basement membrane side up and the excess membrane was trimmed. The edges of them were sutured to the borders of the conjunctiva and the limbus with 10-0 nylon. Topical 0.3% ofloxacin and 1% prednisolone acetate were prescribed every 2 hours postoperatively.

For the next week, the patient improved steadily, having less pain and redness. After a month, the necrotised defect was re-epithelialised completely without inflammation, scar, or symblepharon formation (Fig 2). The eye drops were tapered to four times daily for 2 weeks, twice daily for more 2 weeks, and then stopped.

**Comment**

Subconjunctival atropine has been a useful management for the equine ophthalmic disorder including equine recurrent uveitis, many ulcerative keratopathies, and presurgical and postsurgical cataract extraction. In humans, however, the procedure of subconjunctival injection with atropine has been used infrequently. Our case shows that subconjunctivally delivered atropine should be approached with some degree of caution in humans.

The necrotising conjunctival ulceration in this case covered a large area and was also associated with scleral melting. It was rapidly healed after amniotic membrane transplantation without scleral perforation or symblepharon formation. Transplanted amniotic membrane has been known to provide a thick basement membrane to facilitate epithelial migration, play a part in decreasing inflammation and proteinase activity, and function as an anatomic barrier, keeping the adhesive surfaces apart.13 In our case, some combination of the mentioned characteristics would work for treating a severe necrotising conjunctival ulceration with the potential risk of symblepharon and perforation.

**Traumatic enucleation with chiasmal damage: magnetic resonance image findings and response to steroids**

Gouging has been reported throughout history and this case demonstrates it is still encountered in modern times. Its impact on visual function extends beyond the loss of an eye because of concomitant psychological morbidity.1

**Case report**

We present a case report of a patient who suffered a traumatic enucleation. Our patient is a 24 year old security manager who, while trying to prevent youths from harassing...
Comment

The incidence of traumatic enucleation reported by Erie and colleagues after performing a population based study in Minnesota from 1956–88 was 12 per 100 000 but only one of these was due to an assault. 1

In our case the attacker aimed specifically for the victim’s eyes. Bukhanovsky and colleagues assessed the mental status of 10 eye gougers and found that four of these attackers were psychotic at the time of eye gouging. 2 It is important to look not only at the psychology of the attacker but also the psychological impact on the victim. Our patient went to the psychiatry team weekly for counselling following the trauma.

Suzuki and colleagues reported that if the optic nerve transected is 4 cm or more in length than intracranial complications are likely. These include contralateral visual field loss (which was seen in our case) hypothalamic involvement, subarachnoid haemorrhage, and cerebrospinal fluid leakage. 3

The use of steroids in traumatic optic neuropathy remains controversial. 4 It is thought to restore altered vascular permeability and decreases the swelling of the optic nerve. We saw a marked improvement in the visual field which may be attributed to the steroids.

Cyclodiode laser therapy to control intraocular pressure during pregnancy

Controlling intraocular pressure (IOP) during pregnancy can be problematic because currently available topical ocular hypotensive agents are contraindicated or cautioned in pregnancy. 5 We report the case of a patient with aphakic glaucoma controlled with topical agents, for whom we performed cyclodiode laser therapy, since she wanted to become pregnant. The use of cyclodiode laser therapy for this indication has not been described previously.

Case report

A 30 year old woman was referred to our specialist glaucoma clinic with a diagnosis of aphakic glaucoma in her right eye. She had a past ophthalmic history of chronic uveitis secondary to juvenile chronic arthritis, complications of cataract surgery and subsequent aphakic glaucoma.

At the time of referral her visual acuities were 6/36 in her right aphake eye and 6/5 in the left eye. She had an IOP of 19 mm Hg in her right eye and significant glaucomatous optic nerve. She had a lens replaced after damage was noted. She had become pregnant and it was felt that the IOP was still too high. A third attempt at low dose laser therapy (2000 mW × 40 shots) was partially successful, the IOP being 22 mm Hg 6 weeks later, although this had risen to 28 mm Hg by 4 months. By this time our patient had become pregnant and it was felt that the IOP was still too high. A third attempt at lowering IOP by cyclodiode therapy (2000 mW × 40 shots over 360°) was made, following which the IOP was persistently well controlled at 12–14 mm Hg.

Comment

The use of cyclodiode laser therapy to control IOP in women before and during pregnancy has not been described. It seems a rational choice in treating these patients since the use of topical antiglaucomatous therapy is either contraindicated or cautioned in pregnancy. 6 β Blockers, sympathomimetics, carbonic anhydrase inhibitors, parasympathomimetics, apraclonidine, and prostaglandin analogues have all been shown to have adverse effects in animal fetal models. 7 Understandably, there have been no equivalent studies in the human fetus and results reflecting teratogenesis in laboratory animals cannot be extrapolated to humans. However, some specific examples of adverse effects related to specific topical medications have been quoted in the literature. 8,9 Topical timolol has been shown to cause fetal cardiac arrhythmia and bradycardia. There has been one reported case that correlates the use of acetazolamide in early pregnancy with sacrococcygeal teratoma in the neonate. 10 Prostaglandins are involved in the physiology of pregnancy and thus the use of latanoprost is not advised during pregnancy.

References

2 HORTON JC, WILLEBRAND’S knee of the primate optic chiasm is an artefact of monocular enucleation. Trans Am Ophthal Soc 1997;95:576-609
Pregnancy is usually a period of lower IOP and less therapy may be required than before gestation, although that was not the case with our patient. It could be argued that optic nerve damage over a 9-month period would be minimal such that a mildly raised IOP could be tolerated for the length of pregnancy. However, when glaucomatous damage is severe, it is generally accepted that a low target IOP should be attained. There is a paucity of literature describing the use of local anaesthetics for ophthalmic procedures during pregnancy. However, in a large multicentre retrospective study, exposure to local anaesthetic during early pregnancy was not associated with an increased risk of congenital malformation. Our patient could have been offered augmented filtration or tube implantation surgery but cyclodiode was felt to be less invasive and, ideally, exposure to antimetabolites should be avoided in pregnancy. Cyclodiode is a safe and effective treatment to control IOP before and during pregnancy. The risk of topical medication to the fetus is eliminated and more complex surgical intervention with general anaesthesia is avoided.

Choroidal ischaemic infarction following ocular contusion with small framed spectacles: Hutchinson-Siegrist-Neubauer-syndrome
We read with interest the article by Clarke et al.1 They describe their findings in a 79 year old aphakic woman with a so called non-penetrating injury caused by compression with small framed spectacles. This type of injury is defined to be a contusion/closed globe injury.2

The authors presented a fundus photograph that they interpreted as a “choroidal infarction following blunt injury to the globe.” In the superior hemisphere, there was a large temporally localised area without hypopigmentation and malperfusion of the choroid, corresponding to the segmental structure of the choroidal vasculature.3 However, the findings shown by the authors are more indicative of a segmental choroidal infarction (Hutchinson-Siegrist-Neubauer-syndrome).4 A choroidal rupture following blunt trauma is defined as an arched choroidal defect at the posterior pole following indirect trauma or with other well defined defects in case of direct trauma. We found in all of our patients (7% of all severe contusions) with choroidal rupture a circumscribed and/or sickle shaped configuration.5

By contrast, this clinical picture of a segmental traumatic choroidal infarction was first described by Hutchinson in 1889.6 Siegrist confirmed this new disease in 1895.7 Neubauer observed in three patients the typical segmental choroidal atrophy with corresponding visual field defects.8 Lang and associates explained this severe complication following ocular contusion as follows: as a result of Bell’s phenomenon and excessive cycloplegia, the globe is rotated upwards and moves backwards into the orbit between 0.7 to 1.7 mm.9 An occlusion or rupture of short ciliary arteries may result caused by sudden repositioning of the globe into the orbit,10 which leads to the characteristic choroidal infarction of the corresponding vascular choroidal segments.11 We found Hutchinson-Siegrist-Neubauer syndrome in 1% of all contusions of the Erlangen Ocular Contusion Register.12

Our theory is supported with the recommendation of Vinger, who discussed the need for appropriate protective eyewear for all patients who had undergone intraocular surgery especially in high risk patients—that is, after ICCE surgery.13

Anti-Acanthamoeba efficacy in contact lens disinfecting systems
Hiti et al.14 produced an interesting study investigating the susceptibility of three strains of Acanthamoeba to a PHEM (polyhexamethylene biguanide) based multipurpose solution (MPS), a one-step peroxide system (3% H2O2), and a two-step peroxide system (0.6% H2O2). However, no comment was made regarding
the choice of strains tested, only one of which (A castellanii 4CL) was typical of those that cause keratitis in humans. This isolate belongs to genotype T4, the predominant genotype in Acanthamoeba keratitis.7 Their second strain (A hatchetti 11DS) is of T6 genotype, which, with the exception of one incident, has not previously been reported as causing keratitis. The third strain (A lenticultata 72/2) belongs to genotype T5, and as the authors themselves state “it has not been reported to cause Acanthamoeba keratitis.” Although testing of all three strains was of interest to the microbiologist, the only result that can be extrapolated to clinical practice and be of clinical relevance to the contact lens wearer is that for A castellanii 4CL.

The majority of two step peroxide systems currently available contain 3% hydrogen peroxide. The authors tested a weak peroxide solution (0.6% or 6000 µg/ml), but gave no comment as to why they chose a system with such a low active concentration. The two step system was, however, found to be effective in killing A castellanii 4CL after 9 hour exposure, but not for 1:10 dilution (3000 µg/ml). This result was to be expected as Zanetti et al, in 1995, demonstrated that a 1:2 dilution of a 3% hydrogen peroxide solution killed cysts of A castellanii 4CL after 9 hour exposure, but that a 1:10 dilution (0.3% or 3000 µg/ml) had lost its cidal effect.

The MPS tested was designed for use with rigid gas permeable lenses and contained PHMB at a concentration of 0.0001% (5 ppm or 5 µg/ml). This is higher than that found in the majority of soft lens MPS, which contain 0.0001% PHMB. As the minimum trophozoitidal concentration (MTAC) of PHMB is 1 µg/ml and the minimum cystidal concentration (MCC) is 3 µg/ml, the solution has performed as expected against the clinical strain. Also, a recent study by our group testing the efficacy of a variety of MPS for soft lenses, including one containing 0.0005% PHMB, found this concentration to be cysticidal after the manufacturer’s recommended disinfection time of 4 hours. A reduced effect occurs with 0.0001% PHMB.

One step peroxide systems have been shown to be less effective than two step systems, as the peroxide in the one step solution is rapidly neutralised. Therefore, again, the results for the one step peroxide system were as expected. In addition, a recent cohort study of CL wearers in Hong Kong has shown that lens storage cases were more likely to yield “no bacterial growth” and less likely to yield “heavy bacterial growth” if MPS were used in preference to one step peroxide solutions.

The results for all three solutions when tested against clinically relevant strains of Acanthamoeba were as expected. The authors concluded by recommending the two step peroxide system (0.6% H₂O₂) for overnight storage of contact lenses as an effective disinfectant against Acanthamoeba. However, antimicrobial efficacy is not the only factor that should be considered when advising a CL wearer about a disinfecting solution. Thought must be given to ease of use and personal compliance. It has been suggested that the introduction of MPS has led to a reduced incidence of the infection since 1995. Although MPS may not be as cysticidal as a two step peroxide system, compliance by the CL wearer is higher. In addition, the MPS kills bacteria and fungi within lens cases which reduces growth factors for Acanthamoeba.

CL wearers should practise good hygiene, cases should be changed monthly and only filled with sterile solutions such as MPS—tap water should never come into contact with a lens storage case. Scrubbing of cases, as recommended by the authors, is not frequent with monthly (re)placement. If such measures are taken, then the lens case is kept free of Acanthamoeba.11 The use of MPS with PHMB at 0.0001% is trophozoitidal at 24 hours with partial effect against cysts. If two step multi-purpose solutions are used instead, then the peroxide should be at a concentration of 3% and not 0.6% as recommended by the authors as co-contaminating bacteria, which may be present in the lens case, can produce catalase which aids neutralisation of the active peroxide.

Second Sight
Second Sight, a UK based charity whose aims are to eliminate the backlog of cataract blind in India by the year 2020 and to establish strong links between Indian and British ophthalmologists, is regularly sending volunteer surgeons to India. Details can be found at the charity website (www.secondsight.org.uk) or by contacting Dr Lucy Mathen (lucymathen@yahoo.com).

Specific Eye ConditionS (SPECS)
Specific Eye ConditionS (SPECS) is a not for profit organisation which acts as an umbrella organisation for support groups of any conditions or syndrome with an integral eye disorder. SPECS represents over fifty different organisations related to eye disorders ranging from conditions that are relatively common to very rare syndromes. We also include groups who offer support of a more general nature to visually impaired and blind people. Support groups meet regularly in the Boardroom at Moorfields Eye Hospital to offer support to each other, share experiences and explore new ways of working together. The web site www.eyeconditions.org.uk displays an introduction to the charity and giving direct access to support groups own sites. The SPECS web page is a valuable resource for professionals and may also be of interest to people with a visual impairment or who are blind. For further details about SPECS contact: Kay Parkinson, SPECS Development Officer (tel: +44 (0)1803 524238; email: k@eyeconditions.org.uk; www.eyeconditions.org.uk).

The British Retinitis Pigmentosa Society
The British Retinitis Pigmentosa Society (BRPS) was formed in 1975 to bring together families. The principle aims of BRPS are to raise funds to support the programme of medical research into an eventual cure for this hereditary disease, and through the BRPS welfare service, help members and their families copy with the everyday concerns caused by retinitis pigmentosa. Part of the welfare service is the telephone helpline (+44 (0)1280 860 363), which is a useful resource.
for any queries or worries relating to the problems retinitis pigmentosa can bring. This service is especially valuable for those recently diagnosed with retinitis pigmentosa, and all calls are taken in the strictest confidence. Many people with retinitis pigmentosa have found the Society helpful, providing encouragement, and support through the Helpline, the welfare network and the BRPS branches throughout the UK. (tel: +44 (0)1280 821 334; email: lynda@brps.demon.co.uk; website: www.brps.demon.co.uk)

**Introductory Course in Osteo-odonto-keratoprosthesis (OOKP)**

The University of Brighton Postgraduate Medical School is holding an introductory course in osteo-odonto-keratoprosthesis (OOKP) 20–21 November 2002 in the New Seminar Room, Sussex House, Brighton & Sussex University Hospitals Trust in Brighton. The course will comprise of a variety of lectures with live surgery, two way audio and video links (Stage 1 and Stage 2 OOKP surgery), and examination of patients. Further details: Mrs Erica Strange, University of Brighton, Postgraduate Medical School, Falmer Campus, Brighton, East Sussex BN1 9PH, UK (tel: +44 (0)1273 644 005; fax: +44 (0)1273 644 002; email: e.strange@brighton.ac.uk).

**23rd Annual Conference and Dinner Glaucoma Society (UK & EIRE)**

The 23rd Annual Conference and Dinner of the Glaucoma Society will be held on Thursday 21 November 2002, 8.30am to 5.00pm at the Central Conference Centre, London. The Annual Dinner is from 6.30pm to 10.00pm at The Royal College of Surgeons, London. Conference charges: £60 members; £80 non-members. Price entitles delegates to refreshments, lunch, abstract book, programme, and annual dinner. (Maximum number of places 250—apply now to secure your place). Further details: Janet Flowers, Administrator, 29 Quarry Hill, Grays, Essex, RM17 5BT, UK (tel/fax: 01375 383172; email: glausoc@ukeire.freeserve.co.uk).

**Retinal Detachment Course with international faculty and case presentations preceding Vitrektomie-Kurs—Wetlab**

The Retinal Detachment Course with international faculty and case presentations and Vitrektomie-Kurs—Wetlab will be held 13 February 2003 (in English) and 14–15 February 2003 (in German) respectively, at Verwaltungsgebäude der KA Rudolfstiftung, 1030 Vienna, Boerhanvegasse 8a, Austria. Further details and registration: Firma Askin & Co, Albert-Schweritzer-Gasse 6, A-1140 Vienna, Austria (tel: +43 (1) 979 88 44; fax: +43 (1) 979 88 46).

**Detachment Course with international faculty on: Retinal and Vitreous Surgery with Case Presentations preceding Retina Meeting**

The detachment course with international faculty on: Retinal and Vitreous Surgery with Case Presentations and the Retina Meeting will be held 14–15 March 2003 and 16 March 2003 respectively, in Mexico City, Mexico. Further details: Scientific programme: Prof Ingrid Kreissig, University of Tuebingen, Schleichstr. 12, Breuningerbau, 72076 Tuebingen, Germany (tel: +49 7071 295209; email: ingrid.kreissig@med.uni-tuebingen.de). Local organisation: Prof. Quiroz-Mercado, Prof. Munoz, and Prof Gonzalez “Hospital Luis Sanchex Bulnes”, Asociacion para Evitar la Ceguera en Mexico Vicente Garcia Torres #46, Coyoacan, Mexico DF 04330 (fax: +5255 5659 5928; email: retinamex@yahoo.com).

**16th Annual Meeting of German Ophthalmic Surgeons**

The 16th Annual Meeting of German Ophthalmic Surgeons will be held 8–11 May 2003 in Nürnberg, Germany, Messezentrum. Organised by the Professional Association of German Ophthalmologists Ophthalmic Surgery Group the conference will cover cataract surgery, refractive surgery, glaucoma surgery, vitreoretinal surgery, corneal surgery, eye surgery in developing countries, and orbita, lacrimal and lid surgery. Further details: MCN Medizinische Congress organisation Nürnberg AG, Zerzabelshofstr 29, 90478 Nürnberg, Germany (tel: +49 911 3931621; fax: +49 911 3931620; email: doc@mcnag.info; website: www.doc-nuernberg.de).

**Detachment Course with international faculty on: Retinal and Vitreous Surgery with Case Presentations preceding the Annual Meeting of Iranian Society of Ophthalmology**

The detachment course with international faculty on: Retinal and Vitreous Surgery with Case Presentations preceding Annual Meeting of Iranian Society of Ophthalmology will be held on 29–30 November 2003 and 1–4 December 2003 respectively, at the Razi Conference Center, Hemmat Hyw, Tehran, Iran. Further details: Scientific programme: Prof Ingrid Kreissig, University of Tuebingen, Schleichstr. 12, Breuningerbau, 72076 Tuebingen, Germany (tel: +49 7071 295209; email: ingrid.kreissig@med.uni-tuebingen.de). Local organisation: Dr Arman Masheyekhi, Dr Siamak Moradian, Dept of Ophthalmology, Labbani Finead Medical Center, Pasdaran Ave, Bloostan 9, Tehran, 16666, Iran (fax: +98 21 254 9039; email: labball@hotmail.com).
