Antimetabolites have been shown to enhance the success rate of filtering surgery, although overapplication of these drugs may result in failure of surgery and severe complications. Heuer et al reported the effects of 5-fluorouracil (5-FU) after filtering surgery, and noted that 5-FU should be applied to the eye for several days after surgery. Although the treatment improves the results of filtering surgery, the daily administration is inconvenient and the patient experiences discomfort with each treatment. Therefore, intraoperative single application is effective only for low to moderate risk cases. In addition, a controllable drug delivery system is needed.

Indeed, when it comes to drug delivery, 5-FU might be safer than MMC because delivery can be controlled for several days with 5-FU but for only a few minutes with MMC. When we focused on the development of a safe and effective method to deliver some antimetabolites, we discovered the system that converts ribonucleotides to deoxyribonucleotides, thus inhibiting DNA synthesis. It acts selectively on the cell cycle as described previously. The cells ordinarily do not.

Results: Cell proliferation was inhibited by exposure to 5-FU in a dose dependent manner; however, up to 1000 µg/ml of 5-FU did not affect cell proliferation. Cell proliferation was inhibited by exposure to 5-FU in a time dependent manner with induction of cytosine deaminase following infection of recombinant adenovirus. When 5-FU was removed 3 or 6 days after the treatment, the cells grew again. The effect was reproduced in the in vivo model of subconjunctival cellular proliferation although 5-FU was administrated as eye drops. There were no cases with corneal erosion.

Conclusion: Cell proliferation was inhibited by co-exposure of 5-FU and cytosine deaminase. This new delivery system may merit controlled delivery of 5-FU after filtering surgery.
expression unit of pAxCAwt: a cassette cosmld bearing an expression unit and full length adenovirus type 5 genome with deletions of the E1 and E3 region (a generous gift from Drs I Saito and Y Kanegae). The control vector was AxCAlacZ (from Dr I Saito), which carries the E coli β galactosidase (LacZ) cDNA in the same expression unit. The same virus construction was confirmed by restriction analysis. The clone was then propagated in 293 cells, and purified by sequential protein complex (from Dr I Saito) using the calcium phosphate precipitation method. The viruses generated were modified. Fibroblastic cells were infected at multiplicity of infection (MOI) of 10 with AxCAlacZ, or with AxCACD and AxCACDZ carrying β galactosidase was used as a marker of the cells. Cells were washed with PBS, then harvested, and diluted at a concentration of 10³ cells/ml GM.

Eight week old mice were anaesthetised by an intraperitoneal injection of diluted sodium pentobarbitone. Subconjunctival injections were performed under an ophthalmic surgical microscope. A Hamilton syringe with a 30 gauge needle was inserted into the superior lid until the needle could be observed through the tarsal conjunctiva. A pinhole at the thin bulbar conjunctiva may alter the efficiency of drug delivery, so we used the tarsal conjunctiva although the ultimate target is the bulbar conjunctiva. A total of 10³ cells in 10 µl of GM were injected. Eye drops of 10 mg/ml of 5-FC were administered three times a day beginning immediately after the treatment. The mice were sacrificed at days 1, 5, or 10, and the lids dissected and prefixed by immersion in 4% paraformaldehyde/0.1 M HCl. DNA synthesis was also evaluated with a 5-bromo-2′-deoxyuridine (BrdU) Labelling and Detection Kit III (Roche, Mannheim, Germany) at day 1. Cells were cultured on 96 well plates. Serum free medium with BrdU (50 µl) was added into each well 4 hours before assay. The cells were fixed in 70% ethanol with 0.5 M HCl at −20°C for 30 minutes, then the DNA was fragmented with nuclease at 37°C for 30 minutes. Monoclonal antibody for BrdU conjugated with peroxidase was applied at 37°C for 45 minutes, and the absorbance at 490 nm was then measured.

In vivo study
To evaluate the effect of cytosine deaminase induction in situ followed by eye drops of 5-FC, the method of Khaw et al was modified. Fibroblastic cells were infected at multiplicity of infection (MOI) of 10 with AxCAlacZ, or with AxCACD and AxCACDZ. AxCACDZ carrying β galactosidase was used as a marker of the cells. Cells were washed with PBS, then harvested, and diluted at a concentration of 10³ cells/ml GM.

Statistical analysis
All values are reported as mean (SD). Statistical significance was determined with an analysis of variance followed by Dunnet’s procedure in multiple comparisons. The group without treatment was used as the control. The group without

37°C for 3 minutes, and trypsinisation was stopped by the addition of growth medium with 10% PBS (GM). The suspended cells were centrifuged at 1000 rpm for 3 minutes, after which the pellets were resuspended, diluted to 10³ cells/ml with GM, and seeded into 96 well plates as 10⁴ cells in 100 µl GM. The virus and drug solutions were diluted with GM to reach the final concentrations desired. Of the diluted virus solution or GM, 50 µl were added to each well. The plate was then incubated at 37°C for 30 minutes.

Finally, 50 µl of GM with or without 5-FC (Wako, Osaka, Japan) or 5-FU (Wako, Osaka, Japan) was added to each well. GM, with or without 5-FU or 5-FC, was exchanged every 3 days. The number of cells was evaluated with colorimetric assay using the CellTiter 96 AQ One Solution Cell Proliferation Assay kit (Promega, Madison, WI, USA) at days 0, 1, 3, 6, 9, 12, and 15. According to the manufacturer’s instructions, briefly, cells were cultured on 96 well plates. The cell counting solution was made by mixing 100 µl of GM with 20 µl of the reagent for each well. The GM was removed using multichannel micropipettes, after which 120 µl of cell counting solution was added. The plate was placed at 37°C for 45 minutes, and the absorbance at 490 nm was then measured.

DNA synthesis was also evaluated with a 5-bromo-2′-deoxyuridine (BrdU) Labelling and Detection Kit III (Roche, Mannheim, Germany) at day 1. Cells were cultured on 96 well plates. Serum free medium with BrdU (50 µl) was added into each well 4 hours before assay. The cells were fixed in 70% ethanol with 0.5 M HCl at −20°C for 30 minutes, then the DNA was fragmented with nuclease at 37°C for 30 minutes. Monoclonal antibody for BrdU conjugated with peroxidase was applied at 37°C for 30 minutes. The cells were then incubated with substrate solution at room temperature for 10 minutes, and the absorbance at 405 nm was then measured.

removal of 5-FC, however, was used as the toxic control when the effect of removal of 5-FC was assessed. All experiments in vitro were repeated twice with quadruplicates. Non-parametric analysis was performed using the Kruskal-Wallis test followed by the Mann-Whitney U test. A difference at a level of $p < 0.05$ was considered to be statistically significant.

RESULTS

In vitro study

Cytotoxicity of 5-FU, 5-FC, and adenovirus infection

Firstly, the cytotoxicity of each drug or virus was assessed independently. Various final concentrations from 1 $\mu$g/ml to 1000 $\mu$g/ml of 5-FU and 5-FC were tried. As shown in Figure 2A, up to 1000 $\mu$l/ml of 5-FC does not affect cell growth, although 5-FU inhibits cell growth in a time dependent and dose dependent manner (Fig 2B). The toxic effect of 5-FU was not observed on day 1, but was observed on days 3, 6, and 9.

Cell growth was completely inhibited by 1000 $\mu$g/ml of 5-FU. Next, the cytotoxicity of adenovirus infection was assessed. Infection of AxCACD at various concentrations, up to an MOI of 100, did not produce a cytotoxic effect (Fig 2C).

Cytotoxicity of 5-FC after adenovirus infection

The cytotoxic effect of a combination of 5-FC and AxCACD was assessed. The concentration of 5-FC was 1000 $\mu$g/ml because this concentration did not exert a cytotoxic effect. Virus concentration was varied from MOI 1 to 100. A cytotoxic effect was not observed with either 5-FC or infection of AxCACD, although the combination treatment resulted in a cytotoxic effect in a time dependent and dose dependent manner (Fig 3A). The effect on DNA synthesis was also evaluated. The DNA synthetic activity was reduced by 1000 $\mu$g/ml with 5-FC ($p < 0.001$), whereas moderate titres of AxCACD had no effect. DNA synthetic activity was markedly suppressed by the combination treatment ($p < 0.001$) (Fig 3B).
A cytotoxic effect was observed following treatment with 5-FC and adenovirus infection. However, it is not known whether cell viability is reversible after removal of 5-FC. Accordingly, 5-FC was removed on days 3, 6, or 9, after which the cells were washed three times with GM. Cell viability was then determined after every 3 days. Cell growth was observed at day 9, 6 days after 5-FC removal on day 3, and at day 15, 9 days after 5-FC removal on day 6. Cellular viability did not reverse after 5-FC removal on day 9 in this observation (Fig 4).

In vivo study
Each sample was observed by microscopy and the tissue staining graded as follows: grade 1, no staining; grade 2, patchy staining; grade 3, marked staining. Blue staining means the cells injected remain. Representative photographs of each grade are shown in Figure 5. In vivo cytotoxic effects of gene induction followed by instillation of 5-FC eye drops were observed with a mouse model (Fig 6). Most treated animals showed marked staining of X-gal on day 1, and there were no significant differences among the groups, with almost all of the control cases showing marked staining on days 1 and 5. Many cases that underwent only cytosine deaminase induction or 5-FC application showed staining up to day 10, whereas no cases showed staining of tarsal conjunctiva at day 10 after cytosine deaminase induction followed by 5-FC application. No animals exhibited corneal erosion.

DISCUSSION
Both 5-FU and MMC have been used as an adjunctive treatment in glaucoma filtering surgery, although MMC is preferred because of its more convenient application. It is easy to apply and is not unpleasant for patients, although application must be limited to a few minutes during surgery and it may be difficult to select the appropriate dosage for each individual eye. In contrast, 5-FU can be administered over a course of several days after surgery. Thus, with the use of 5-FU it is easier to avoid the problems of overdosage, although its administration is less inconvenient for both patients and surgeons. Based on results of previous studies, various factors that are released gradually after administration were studied, which may reduce the inconvenience of 5-FU administration. However, the material should be removed surgically when the drug effect exceeds optimal conditions. Recent studies revealed a possible beneficial effect of a single application of 5-FU during surgery. However, the appropriate dosage for each case appears to be different. Intraoperative single application is presently effective only for low to moderate risk cases, and a more controllable drug delivery system is needed.

In this study, we showed that cytosine deaminase induction and 5-FC administration leads to production of 5-FU in vitro and in vivo. Vector administration and 5-FC eye drops induce...
Further investigation is needed in rabbit and monkey models mimicking the clinical situation, although we have shown the feasibility of a new drug delivery system.

ACKNOWLEDGEMENTS

We thank Drs I Saito and Y Kanegae for their generous gifts of materials. Supported in part by grants from the Japanese Ministry of Education, Science and Culture.

lesser toxicity to other cells, such as those of the corneal epithelium, and the produced 5-FU will maintain an ischaemic bleb.

We used the cytosine deaminase gene, which converts 5-FC to 5-FU and enhances drug sensitivity of the cells involved. This type of application is referred to as suicide gene therapy.14 Sakamoto et al18 reported the effectiveness of herpes simplex virus thymidine kinase and ganciclovir in a model of proliferative vitreoretinopathy. While this information is applicable, we have the great advantage of previous experience in the use of 5-FU after filtering surgery. With regard to cancer gene therapy, the effect of drug removal has not been described, but our data showed that removal of 5-FU resulted in return of cell viability after several days of treatment. It would be advantageous of course to have a gradual release delivery system. Additionally, the switching system of Cre-loxP may be beneficial in cases of overdosage.15,16 Using this system, production of cytosine deaminase can be halted by means of another viral infection. We also tried to enhance the effects of 5-FC by accelerating the toxic conversion with co-induction of cytosine deaminase and uridine phosphorylase, which enables conversion from 5-fluorouracil to 5-fluorouridine (Fig 1). However, no enhancement of cellular toxicity was observed (data not shown). It seemed cytosine deaminase is critical in this cascade.

One problem is how to deliver cytosine deaminase into the subconjunctival space. In an attempt to do this, we used an adenovirus vector to deliver cytosine deaminase. By its nature, adenovirus is not incorporated into genomic DNA, although retrovirus is. As most adults have an acquired immunity to adenovirus, the vector is avoided within a few months. However, rather than being a problem, this seems to increase safety. The various safety levels needed to be examined closely before clinical use, but the adenovirus vector appears to be powerful and safe for in vivo use compared to others available, such as retrovirus and liposome based vectors.17

A new delivery system for 5-fluorouracil using prodrug and converting enzyme
