Histopathological findings in filtering blebs with recurrent blebitis

We report clinical courses and histopathological findings of excised blebs from two patients with recurrent blebitis.

Case reports

Case 1

A 79 year old man with a past history of lung cancer and diabetes mellitus underwent trabeculectomy with 5-fluorouracil in his right eye for a diagnosis of primary open angle glaucoma (POAG) in 1989. In January 1994, bleb leakage from an avascular bleb was confirmed for the first time and prophylactic topical erythromycin was applied. In September 1994, he experienced ocular pain and hyperaemia in his right eye and blebitis was diagnosed. Culture of aqueous humour was performed in February 2001. Histological examination of the bleb specimen revealed an attenuated epithelium with goblet cell depletion and hyaline change with a loss of inflammatory responses in the lamina propria.

Comment

According to previous reports, the epithelia of leaking blebs following adjunctive use of antimetabolites shows focal or general thinning. In cases of leaking bleb after filtering surgery without the use of antimetabolites, Srinreich et al reported similar epithelial thinning, while Addicks et al reported normal epithelium. Both of our cases were similar to the former. Moreover, there was goblet cell depletion in both of our cases. Mucin is a highly adhesive substance secreted from goblet cells and mostly forms as surface mucin over the cornea or conjunctiva, which has an important function as a physical, biological barrier on the ocular surface, such as elimination of foreign bodies or control of micro-organisms. Thus, histological findings of these two cases of recurrent bleb infection are compatible with dysfunction against bacterial infection.

Inflammatory reaction in the stroma of the bleb is decreased with the use of mitomycin C, while cases of leaking blebs without antimetabolites reportedly show moderate subconjunctival inflammation. Case 2 in the present study, without the use of antimetabolites, had a low inflammatory reaction. Poor immune response may be related to the poor blood supply in these ischaemic blebs and compatible with the poor immune response to bacterial infection.

Waheed and his colleagues reported clinical characteristics of 12 eyes with recurrent bleb related infections and they concluded that eyes that have been successfully treated for bleb related infection remain at risk for recurrent infection. Histopathological findings showing thinning and breakdown of epithelial structures in the present study may explain this findings.

Retinal detachment surgery in district general hospital: an audit of changing practice

Despite advances in the techniques of vitreoretinal surgery, rhegmatogenous retinal detachment (RBD) continues to pose a serious
threat to vision. In the past, general ophthalmologists in the United Kingdom undertook most RRD surgery, with only the “more complex” cases being referred to retinal specialists. The recent trend towards subspecialisation has led to increasing numbers of primary RRD being managed by vitreoretinal surgeons in tertiary referral centres.1

We conducted an audit to determine the current success rate of primary RRD surgery in our subregion (south west subregion, SWSR). SWSR consists of the catchments of four district general hospitals (DGH) in Devon and Somerset (population 1.2 million). A previous subregional audit in 1991 showed that all consultant ophthalmologists undertook primary RRD repair, achieving a success rate of 71% with one operation.2 Since then, retinal subspecialisation has meant that all RRDs are managed by three retinal specialists (CJ, PS, RG) in their individual DGHs, providing a subregional surgical retinal service. An informal cross cover arrangement exists between the three DGHs, with the result that patients are very rarely referred out of the subregion.

Case notes of all patients who underwent surgery for primary RRD from January to December 1999 were retrospectively reviewed. Case ascertainment was achieved by reviewing theatre logbooks and identifying all vitreoretinal procedures that took place during 1999. A single investigator (RL) collected data for all patients: total cases of RRD were 71%, and a success rate of greater than 71%. Data were collected for all of the patients: 1999 was chosen so as to "catch" the primary success rate and provide a true comparison with the previous audit. The case mix was comparable (Cambridge VRU 80%, SWSR 83%, St Thomas’s 84%, Moorfields 80%, p>0.05, χ² test). However, it is debatable whether retinal reattachment achieved with silicon oil in situ can be considered “stable.” After excluding eyes with silicon oil still in situ, the “oil-out primary success rate” was comparable (Cambridge VRU 80%, SWSR 83%, p>0.05, χ² test).

The primary success rate, although significantly improved, was not 100%. Improvement on our “early” failures, mostly due to technical errors, can be achieved by appropriate choice of surgical technique. For the “late” failures, all consequence of PVR, improvement may depend on the identification of “at-risk” cases, and the selective use of an “anti-PVR cocktail.”

To conclude, we have shown that the primary success rate of RRD surgery has improved following a change in practice towards retinal subspecialisation in our subregion. The anatomical success and functional outcome were comparable to results from other VRUs in the United Kingdom.3,4 The benefits of providing a local vitreoretinal service, in contrast to referring patients to a VRU in a tertiary centre, include prompt on-site surgical access, and the availability of rehabilitation from family and friends locally to aid visual rehabilitation in the postoperative period.

*p<0.05, Wilcoxon test.

In 1991, all consultant ophthalmologists in our subregion undertook primary RRD surgery, each managing on average 8.2 cases per year. In the current audit cycle, the caseload has increased to 42 cases per consultant, with three retinal specialists managing all the RRD. Assuming there was no significant change in the detachment case mix between 1991 and 1999, the improvement in the primary success rate is most likely to be associated with the advent of vitreoretinal subspecialisation.5 Results of RRD surgery from three vitreoretinal units (VRU) in the United Kingdom1,6 provided indicators for comparison. With the exception of pseudophakic rate (Cambridge 12%, SWSR 24%), our case mix was most comparable to the Cambridge subregion, with both series describing RRD from geographically well defined populations. Initially, there would appear to be significant differences in the primary success rate between the four studies (Cambridge VRU 90%, SWSR 85%, St Thomas’s 84%, Moorfields 80%, p<0.05, χ² test). However, it is debatable whether retinal reattachment achieved with silicon oil in situ can be considered “stable.” After excluding eyes with silicon oil still in situ, the “oil-out primary success rate” was comparable (Cambridge VRU 80%, SWSR 83%, p>0.05, χ² test).

The primary success rate, although significantly improved, was not 100%. Improvement on our “early” failures, mostly due to technical errors, can be achieved by appropriate choice of surgical technique. For the “late” failures, all consequence of PVR, improvement may depend on the identification of “at-risk” cases, and the selective use of an “anti-PVR cocktail.”

To conclude, we have shown that the primary success rate of RRD surgery has improved following a change in practice towards retinal subspecialisation in our subregion. The anatomical success and functional outcome were comparable to results from other VRUs in the United Kingdom.1,4 The benefits of providing a local vitreoretinal service, in contrast to referring patients to a VRU in a tertiary centre, include prompt on-site surgical access, and the availability of rehabilitation from family and friends locally to aid visual rehabilitation in the postoperative period.
Do climatic variables influence the development of posterior vitreous detachment?

Posterior vitreous detachment (PVD) is a common condition after the fifth decade of life. Synchrony of the vitreous progresses in proportion to age, creating holes in the posterior hyaloid membrane and allowing PVD to occur. The incidence of rhegmatogenous retinal detachment is generally accepted to be season dependent, with a higher incidence in the summer months. However, there is no evidence that PVD is season dependent. We performed this study to determine whether there is any correlation between ambient temperatures, humidity, or solar radiation on the incidence of PVD.

Case patients

Patients were selected for this study from the eye casualty database at Oxford Eye Hospital. All patient records, which have been diagnostically coded as acute PVD over a 2 year period, were reviewed. Cases where there was a precipitating cause for PVD such as blunt trauma, retinal vascular disease, diabetic retinopathy, previous surgery, or laser treatment were excluded. Only cases with spontaneous PVD were included in the study.

We used three environmental variables—mean daily temperatures in degrees centigrade (°C), percentage relative humidity (both ambient and pericentral corneal ulcer. Cultures yielded *Staphylococcus aureus*, *Streptococcus viridans*, and *Serratia marcescens*). The patient was treated with intravitreal injection of 20% dexamethasone and antibiotics. On the next day, she noted a decrease in vision in the eye.

However, we postulate that increasing air temperatures and the incidence of PVD. The lack of any previous literature on this subject makes it difficult to draw any conclusions about the mechanism for an increase in PVD occurrences with increasing temperatures. However, we postulate that increasing physical activity and dehydration associated with increasing temperatures may have a role to play.

Further work is necessary in order to investigate the effect of increasing temperatures and dehydration on the biochemical structure of the vitreous.

7. Ocular and systemic posaconazole (SCH-56592) treatment of invasive Fusarium solani keratitis and endophthalmitis

An emmetropic 42 year old immunocompetent woman with 6.6 vision developed left eye blurred vision while wearing cosmetic soft contact lenses. She presented on 28 July 2000 to her ophthalmologist, who noted deep stromal infiltration accompanying a 2 × 3 mm pericentral corneal ulcer. Cultures yielded *Staphylococcus aureus*, *Streptococcus viridans*, and *Serratia marcescens*. The patient was treated with intravitreal injection of 20% dexamethasone and antibiotics. On the next day, she noted a decrease in vision in the eye.

We also found a strong association (p = 0.028) between the air temperatures of the previous week and the number of weekly occurrences and the results were very similar to the same week.

Comment

Vitreous liquefaction, which advances with increasing age, is an important event in the pathogenesis of PVD. In our study there was no evidence of a cyclical pattern for the weekly or monthly occurrences, therefore we modelled the number of PVD cases directly as a function of the air temperature. Our data suggest a highly significant correlation between weekly average temperatures and the incidence of PVD.

We used three environmental variables—humidity, air temperature, solar radiation—to predict the occurrence of PVD. A model that included both air temperature and humidity had a significant and direct effect on the log transformation (p = 0.035) between weekly averaged air temperature and the number of occurrences of PVD (Fig 1). However, we did not find a significant association between weekly occurrences of PVD and relative humidity or solar radiation.

We found a significant increase in the variance of the number of occurrences of PVD from 4.23 to 5.49 cases per week between 1996 and 1997 (t test, p = 0.0019), so we included year in all models (Fig 1).

We first fitted a model including relative humidity, air temperature, solar radiation, and year. There was evidence of a strong association (p = 0.035) between weekly averaged air temperature and the number of occurrences of PVD (Fig 1). However, we did not find a significant association between weekly occurrences of PVD and relative humidity or solar radiation.

Fusarium solani. Initial therapy with tobramycin was followed by high dose topical hydroquinones, whereafter the infection, continuing unabated, was construed to be fungal keratitis. High doses of amphotericin B both topical and intravenously, natamycin, and ketoconazole were administered, along with topical fortified cephazolin, neosporin, and atropine. Despite these, the lesion spread to involve much of the corneal periphery (Fig 1), and repeat corneal cultures confirmed the presence of amphotericin B resistant Fusarium spp (MIC 24:48 hours in µg/ml: amphotericin B 2:2; natamycin 32:32; posaconazole 1:8).

On 1 September 2000, the anterior chamber was filled with fibrin with a central corneal descemetocele, and near total corneal infiltration, affording only a hazy view of the peripheral iris. The fibrin clot was integrated with the central iris, and the lens was not visible. Ultrasonography suggested anterior segment involvement only. Posaconazole (SCH 56592), an investigational broad spectrum triazole, was obtained from Schering-Plough Research Corporation and administered at 200 mg four times daily orally, with hourly topical ocular application of the same suspension (10 µg/0.1 ml). A compassionate use investigative new drug (IND) approval for topical ocular application of posaconazole was requested from, and promptly issued by, the Federal Drug Administration, and informed consent was obtained through an institutional review board approved protocol. Treatment commenced 5 September 2000, when aqueous tap reconfirmed presence of Fusarium, which was susceptible in vitro to posaconazole.

Within the first week of 2 hourly topical application of posaconazole oral suspension (100 µg/ml), along with 800 mg orally of the same, there was significant clearing of the corneal periphery. The fibrin clot melted concentrically, revealing its attachment to the descemetocorneal anterior and central iris posteriorly.

With further clearing of the infectious inflammatory clot, the anterior descemetocele became effectively unplugged. The globe decompressed through the open corneal ulcer providing the impetus for urgent penetrating keratoplasty on 20 September 2000. Histology revealed innumerable septate branching fungi within the corneal and iris stroma.

One week later, further remarkable improvement was noted. Despite the ominous surgical history, >90% of the fibrin clot had cleared. Diagnostic vitrectomy yielded posaconazole at a concentration of 0.25 µg/ml in the vitreous (and 1.2 µg/ml in the plasma) on 26 September 2000. Vision improved markedly, with good projection to confrontational light throughout the periphery. The clarity of the transplant and anterior chamber now revealed a dense white cortical cataract, with residual fibrin clot inferior to the graft-host interface. Topical corticosteroid therapy was cautiously introduced. By 30 October 2000 the patient’s condition was further improved, and elective combined phacoemulsification with planned aphakia was carried out on 11 January 2001. Branching elements of the Fusarium were histologically confirmed to have penetrated the surgically removed anterior cortex and capsule, but all subsequent cultures were negative, and aqueous tap confirmed posaconazole to be present at a level of 0.9 µg/ml, with a plasma level of 1.6 µg/ml.

At 16 months, on 4 December 2001, vision remained stable with good colour vision and 360 degree peripheral visual function. The visual axis was clear, with two small clear operculi in the otherwise opaque residual posterior capsule (Fig 2). Visual acuity was 6/30 using aphakic correction, with no afferent pupil defect. Prognosis for eventual lens replacement, posterior capsulotomy, and visual rehabilitation of this eye now appeared very good. This excellent outcome is not anticipated for invasive Fusarium of the eye.

In summary, a healthy woman with amphotericin and natamycin resistant Fusarium spp keratitis, progressing to invasive keratrhitis and endophthalmitis, recovered with good retinal function via an apparently rapid response of the Fusarium to systemic and/or topical posaconazole. The ocular penetration of posaconazole was confirmed on separate occasions by aqueous and vitreous analysis.

World Sight Day and cataract blindness

Age related cataract remains the major cause of blindness throughout the world. It is estimated that the present number of 20 million of cataract blind will double by the year 2020. The main reasons for low uptake of cataract surgery in developing countries are poor surgical outcome and high cost. Various strategies have been suggested by the global initiative “Vision 2020: the right to sight” to reduce cataract blindness.

In Nepal, on “World Sight Day,” Lahan Eye Hospital and Tilganga Eye Centre jointly conducted a one-week cataract surgical “workshop” from 8–13 October 2001. A total of 1542 patients with operable cataract were identified in 49 screening camps in rural areas of south east Nepal and transported to Lahan Eye Hospital. During 6 days 2292 cataract operations were performed, of which 2167 were cataract extractions (range 286–594 per day).

The operations were performed by six experienced eye surgeons using a sutureless non-phaco technique, removing the nucleus.

Failure of amniotic membrane transplantation in the treatment of acute ocular burns

We read with interest the article by Joseph et al. It is to be appreciated that they have come forward to report the negative results of their study along with the need of an upgraded classification for the chemical burn. The authors must be congratulated for highlighting the pitfalls of amniotic membrane transplantation (AMT) in acute cases with sufficient scientific explanation.

Whenever a new technique is described it is aggressively followed without realising the consequences. The authors have very rightly suggested that the most important strategy for the management of thermal and chemical burns in the acute stage is to reduce inflammation, promote healing, prevent scarring, and epithelialisation of the cornea. It is reported in the literature that AMT does help in all these three conditions at the acute stage of burns for which the procedure is advocated, but when used to some extent? It is essential to have some amount of healthy conjunctival tissue for graft to take up. Further, rather than performing the AMT at an acute stage, there should be some time lag between burn and surgery to help to reduce inflammation, thus allowing the surgeons to perform an elective surgery. Regarding the stage of the chemical burn, the authors have rightly pointed out that there is a remarkable limitation in modified Roper Hall's classification at grade IV. Do the eyes with 100% limbal ischaemia behave in the same way as those with 55% ischaemia?

It was somehow back in 1984 and a modified classification was suggested in these eyes before keratoplasty as a prognostic factor. However, the same factor was restricted to healed lesions and now the time has come for the modification of AMT. Once again, we would like to commend the authors for their boldness and wonder how many other corneal surgeons would have felt the same.

“No-needle” sub-Tenon’s anaesthesia

We read with interest the letter from Amin et al. suggesting a modification of the sub-Tenon local anaesthesia injection procedure. They advocate the use of a Venflon needle to penetrate the conjunctiva, with subsequent advancement of the cannula before anaesthetic injection. We are concerned that the use of a sharp needle should be recommended so close to the eye. Amin et al point out that the needle tip is clearly visible at all times and therefore at “minimal risk” of puncturing the eye. However, once under the conjunctiva, the needle is not necessarily “clearly” visible, and if conjunctival haemorrhage should occur then it will quickly become obscured. We do not think it sensible to place a sharp needle close to the eye when an effective and well proven alternative delivery system has already stood the test of time.

In his editorial on local anaesthetic injection techniques for cataract surgery, Smerdon rightly emphasises the risk of ocular penetration for all techniques involving needles, and highlights the Royal College of Ophthalmologists’ local anaesthesia survey which demonstrated the relative safety of sub-Tenon’s and topical anaesthesia. We agree with him that when discussing an anaesthetic technique with a potential for high volume, it is not the expert anaesthetist/ophthalmologist who should be borne in mind, but rather the less skilled person, possibly less familiar with ophthalmic anaesthetic techniques, or in training, who may be required to administer a block. It is in this setting that the use of a needle very close to the eye is, in our opinion, an unwarranted risk. Surely the “no needle” sub-Tenon’s technique is just as effective, and safer.

Trachoma and recurrent trichiasis

It was with great interest that I read the recent article by al Arab and co-workers. This work clearly shows that endemic blinding trachoma continues to be a major health problem in this area of the Nile Delta, quite close to Cairo.

My attention was particularly drawn to the high rate of recurrence among those who had trachoma surgery. Overall, 44% of cases who had had surgery had recurrent trichiasis. It would be most interesting to look at the time that had elapsed between surgery and the time of examination. Some have argued that the recurrence rate from trichiasis reflects poor or inadequate surgery. Others have alluded to the fact that the tarsal striping trachoma is of a progressive nature and that trichiasis is likely to recur because of ongoing scarring, even after otherwise successful surgery. Information of the elapsed time would help explore the scenario.

A re-analysis of astigmatism correction

In a recent perspective by Morlet et al. there are a number of omissions and fundamental errors of content that lead to erroneous conclusions. These significant inaccuracies overlooked in the review process compromise the article’s broad contribution.

In Morlet et al’s attempt to detail “the use and limitations for the analysis of change in astigmatism” (p 1127) they display an incomplete understanding of the subject. They have made a valiant attempt to assemble a comparison of historical and contemporary references on a subject of significant interest, but key material has been omitted or misquoted. This has resulted in leading statements in the article, in both the body of the text and even the conclusion, that require re-evaluation and substantial revision.

The most obvious omission is the paper’s absence of any discussion of the difference vector, a precise measure of surgical success that is described in reference 7. When the difference vector is related to the treatment (that is, TIA or target induced astigmatism vector) one has an extremely useful relative value of success of such astigmatism treatment. Morlet et al have overlooked this key vectorial entity and struggle to find any useful alternative. In sharp contrast Dr Doug Koch, editor of the Journal of Cataract and Refractive Surgery, in his editorial on “The re-analysis of astigmatism issue of January 1999” (p 1131) described the difference vector and the index of success as “remarkably useful and intuitive means of understanding the effects of the surgery.”

The authors state more than once for their principal foundation of the article that “Vector analysis alone does not provide any indication of the relative value of the surgical procedure” (p 1132). These statements are erroneous, and the authors’ failure to discuss or dispute the value of the difference vector and index of success leaves the assertion unsupported and lacking credibility. If the surgical induced astigmatism vector (SIA) (i.e. further translation) was the only product of vector analysis, indeed vector analysis would be a limited tool. This seems to be Morlet et al’s contention. This is far from the truth and as a result the restatement in the conclusion that “vector analysis does not give a measure of surgical outcome” (p 1134) is factually inaccurate.

In addition, their interpretation that the off-axis effects of treatment at 45° to the surgical plan (that is due to the original astigmatism) could not be more accurately be termed “torque,” the component of the SIA that has been effective in reducing astigmatism. The relevant reference describing flattening, steepening, torque, and effect of off-axis treatments has been omitted from the attempt at a comprehensive list of relevant published material. The phenomena of rotation and torque are fundamentally different physical processes. The polar value at 45° to the “surgical plane” (p 1131) quantifies the torque which causes an increase in the existing astigmatism associated with its change in orientation. It does not properly gauge the cylinder value due to its inherent non-concurrent change in the amount of existing astigmatism occurs. Rotation includes some associated flattening (or steepening) effect occurring as a result of the SIA.

The articles conclusion that “a better evaluation of the effect of astigmatism axis requires the use of the ‘by the rule’ or mirror equivalent axis notation, or by a manual scoring method to produce an outcome summary measure” (p 1134) is convoluted and unwarranted. If implemented this would adversely affect the comprehension of astigmatism outcome analysis by the average general ophthalmic or refractive surgeon.

It is unfortunate the reviewers of this paper did not direct the authors to other significant fallacies that merited revision. The statement “vector analysis is only valid in the early post-operative period” because “the healing response has modified the induced astigmatism” (p 1131) shows the authors’ failure to understand that the healing response cannot be divorced from the surgical process. It is part of it. The amount of astigmatism correction (SIA/TIA) achieved will vary with trends over time when examining aggregate data, and this phenomenon requires surgeons to examine outcomes facilitating adjustment of new programs based on long term (at least 6 months) and not immediate outcomes. The later statement “the use of vector analysis over time is conceptually invalid, because unlike the initial surgical event, the wound healing process is continuous” (p 1132) is seriously flawed. Vector analysis is an essential component of this refinement process. In fact, vector analysis could be used to determine the astigmatic effect of the healing process itself by comparison of data at various stages in the postoperative period.

The recommendations promoted by Morlet et al introduce greater complexity in an already complicated subject. For example, mixing negative and positive cylinder notation is unnecessary. The technique put forward (p 1131 and equation 20) does not address the changes that occur in corneal shape as measured by keratometry and topography, and cannot be readily applied when targeting non-zero goals associated with incomplete or off-axis refractive astigmatism treatment.

It is probable that the authors are careless in raising phantom “problems” (p 1128) for planning techniques based on incorrect quoting of information (such as reference 33). The merits of this customised treatment technique are that refractive as well as keratometric data are employed (contrary to its misrepresentation that the technique “only uses keratometric data for the planning of refractive surgery” (p 1128)).

Morlet et al’s unfortunate statement of opinion that “a lack of critical evaluation” has resulted in “the surgical vectors that are de facto standard used in most reports concerning the surgical management of astigmatism” (p 1132) is not shared by many experienced investigative surgeons in the field. This has been shown by its admitted prevalence by the authors, and the uselessness of vectorial analysis in understanding the surgical process. Indeed, many of the erroneous statements and omissions in the perspective article might lead one to ask where the “lack of critical evaluation” actually lies.

BOOK REVIEW

The Hole In My Vision: An Artist’s View of His Own Macular Degeneration.

This text provides an illuminating and unique insight into the entoptic phenomena induced by the development of age related macular degeneration. Written primarily by a distinguished ophthalmic artist and photographer, it records his visual impressions of the development of age related macular degeneration in his own retinas during a 10 year period. His method of inducing and illustrating his entoptic phenomena is fascinating and the correlation with the clinical fundus findings of his attending ophthalmologists is quite remarkable. The effect of laser photocoagulation is clearly described from a patient’s perspective.

This book is written in large print for the lay sufferer and ophthalmic professional alike. It is an easy read with plentiful illustrations and should occupy the bookshelf of all concerned with this potentially blinding disorder. Profits derived from the sale of this book will be used to support age related macular degeneration research.

NOTICES

Childhood blindness

The latest issue of Community Eye Health (No 40) discusses new issues in childhood blindness, with an editorial by Clare Gilbert, senior lecturer at the International Centre for Eye Health. For further information please contact: Journal of Community Eye Health, International Centre for Eye Health, Institute of Ophthalmology, 11–43 Bath Street, London EC1V 9EL, UK (tel: +44 (0)20 7608 6910; fax: +44 (0)20 7250 3207; email: eyeresource@ucl.ac.uk; website: www.jceh.co.uk). Annual subscription (4 issues) UK£25/US$40. Free to workers in developing countries.

International Centre for Eye Health

The International Centre for Eye Health has published a new edition of the Standard List of Medicines, Equipment, Instruments and Optical Supplies (2001) for eye care services in developing countries. It is compiled by the Task Force of the International Agency for the Prevention of Blindness. Further details: Sue Stevens, International Centre for Eye Health, 11–43 Bath Street, London EC1V 9EL, UK (tel: +44 (0)20 7608 6910; email: eyeresource@ucl.ac.uk).

Second Sight

Second Sight, a UK based charity whose aims are to eliminate the backlog of cataract blind in India by the year 2020 and to establish strong links between Indian and British ophthalmologists, is regularly sending volunteer surgeons to India. Details can be found at the charity website (www.secondsight.org.uk) or by contacting Dr Lucy Mathen (lucymathen@yahoo.com).

Specific Eye Conditions (SPECS)

Specific Eye Conditions (SPECS) is a not for profit organisation which acts as an umbrella organisation for support groups of any conditions or syndrome with an integral eye disorder. SPECS represents over fifty different organisations related to eye disorders ranging from conditions that are relatively common to very rare syndromes. We also include groups who offer support of a more general nature to people with retinitis pigmentosa. Part of the welfare service is the telephone helpline (+44 (0)1280 860 363), which is a useful resource for any queries or worries relating to the problems retinitis pigmentosa can bring. This service is especially valuable for those recently diagnosed with retinitis pigmentosa, and all calls are taken in the strictest confidence. Many people with retinitis pigmentosa have found the Society helpful, providing encouragement, and support through the Helpline, the welfare network and the BRPS branches throughout the UK. (tel: +44 (0)1280 821 334; email: lynda@brps.demon.co.uk; web site: www.brps.demon.co.uk)

Ophthalmic Anesthesia Society (OAS) 16th Scientific Meeting

The 16th Scientific Meeting of the OAS will be held on 4–6 October 2002 in The Westin, Michigan Avenue, 909 North Michigan Avenue, Chicago, USA (reservations +1 800 228 3000). Further details: OAS, 793-A Foothill Blvd, PMB 110, San Luis Obispo, CA 93405, USA (tel: +1 805 771 8300; web site: www.eyeanaesthesia.org).

BEAVRS Meeting

The next BEAVRS meeting will be held in the Dalmahoy Hotel near Edinburgh on 31 October to 1 November 2002. Further details: Susan Campbell, Medical Secretary, Gartnavel General Hospital (email: susan.j.campbell@northglasgow.scot.nhs.uk).

The British Retinitis Pigmentosa Society

The British Retinitis Pigmentosa Society (BRPS) was formed in 1975 to bring together people with retinitis pigmentosa and their families. The principle aims of BRPS are to raise funds to support the programme of medical research into an eventual cure for this hereditary disease, and through the BRPS welfare service, help members and their families cope with the everyday concerns caused by retinitis pigmentosa. Part of the welfare service is the telephone helpline (+44 (0)1280 860 363), which is a useful resource for any queries or worries relating to the problems retinitis pigmentosa can bring. This service is especially valuable for those recently diagnosed with retinitis pigmentosa, and all calls are taken in the strictest confidence. Many people with retinitis pigmentosa have found the Society helpful, providing encouragement, and support through the Helpline, the welfare network and the BRPS branches throughout the UK.
