3.1 - GENERAL PRINCIPLES OF GLAUCOMA TREATMENT

The purpose of this chapter is to give a summary overview and it is not meant to be an all-inclusive text.

Figure 3.1. THE WHOM-TO-TREAT GRAPH The rate of ganglion cell loss and resulting functional decay is very different among different glaucoma eyes. Quality of life is clearly reduced when visual field defects become severe, cf. the severe functional impairment. Line A represents the effect of aging alone. In glaucoma loss of visual function is often much more rapid. An older patient, diagnosed late in life, with a moderate rate of progression (B) has a much lower risk of developing severe functional impairment than a younger patient with the same amount of field loss at diagnosis and rate of progression (C). A very slow rate of progression may be tolerated by the patient and treatment left unchanged (D), while a rapid rate of progression (E) needs a considerably lower target pressure.

It needs to be remembered that it is the extent of binocular visual field or the field of the better eye that largely determines the patient’s quality of life, while the rates of progression of each eye separately are needed to determine treatment.

To assess the likely Rate of Progression (RoP) is an important part of patient management and the measured rate is a very important factor that should determine target pressure and treatment intensity (See Ch. Introduction) [1, D]. Many studies have found that progression is usually linear[1,4], but the goal of intensifying treatment is to decrease rate of progression.
The “Terminology and Guidelines” project was entirely supported by the EGS Foundation.

Please observe that perimetric printouts of progression using the MD or VFI indices are age-corrected, so that a normal eye would not show any age-related deterioration over time.

The goal of glaucoma treatment is to maintain the patient’s visual function and related quality of life, at a sustainable cost. The cost of treatment in terms of inconvenience and side effects as well as financial implications for the individual and society requires careful evaluation (See Ch. Introduction). Quality of life is closely linked with visual function and, overall, patients with early to moderate glaucoma damage have good visual function and modest reduction in quality of life, while quality of life is considerably reduced if both eyes have advanced visual function loss.

Glaucoma is still a leading cause of blindness in Europe. A considerable percentage of glaucoma patients become blind in both eyes or encounter serious field loss in both eyes. Major risk factors for glaucoma blindness are the severity of the disease at presentation and life expectancy. A 60-year-old patient with bilateral moderate visual function damage at diagnosis has a greater risk of blindness than an 85-year-old patient with a similar amount of damage. Similarly, a young patient with mild bilateral damage is at much larger risk of disability in his lifetime than an 80-year-old patient with moderate unilateral disease. Thus, treatment must be individualised to the needs and rate of progression (RoP) of each patient (See Fig. 1 Ch. Introduction) [I,D]. The risk of ever encountering loss of quality of life from glaucoma should determine target pressure, intensity of treatment, and frequency of follow-up [I,D].

Thus, patients with severe functional loss or younger patients with manifest disease should have more aggressive treatment and closer follow-up than patients with little or no risk, e.g., very old patients with early field loss or unilateral disease [I,D]. Glaucmoma suspects, e.g., patients with elevated IOP and otherwise normal findings, have even smaller risks.

In most patients with advanced glaucoma and reasonable life expectancy, aggressive IOP lowering treatment might be recommended [I,D]. Very old patients with mild loss, relatively low IOP levels and significant health problems, might prefer being followed without treatment (See also Ch. Introduction) [I,D]. When treatment options are discussed with a patient, his general health status and personal preferences must be considered and respected. It is also important to ensure that patients are able to comply and persist with therapy [I,D].

Disease progression rates (RoP) in POAG, the most common form of glaucoma, differ very much between patients, from rapid to very slow. This makes it necessary to determine the RoP in patients with manifest glaucoma (See Fig. 1 Ch. Introduction) [I,D]. Many patients with POAG/NTG show no or only small deterioration despite years of follow-up, while rapid progression is more common in others, e.g. in exfoliation glaucoma. Glaucmoma patients may continue to show progression despite treatment, even with IOP levels within the statistically normal range. Relying on tonometry alone for glaucoma follow-up is, therefore, insufficient regardless of IOP level. Determining the rate of visual field progression is a new standard in glaucoma care. The EGS recommends three visual field tests per year for the first two years after...
diagnosis to make it possible to identify rapidly progressing patients [I,II,D]. After two years of perimetric monitoring without progression being detected the frequency of tests may be reduced [I,II,D]. Once the progression rate has been determined the target pressure is re-evaluated and be based on the measured rate of progression and IOP values measured during the follow-up time [I,II,D]. Risk factors are then less important than at diagnosis (See Ch. 2.2).

**Individualized glaucoma treatment aims at providing glaucoma management tailored to the individual needs of the patient; patients with severe functional loss or younger patients with manifest disease should have more aggressive treatment and closer follow-up than patients with little or no risk, e.g., patients with ocular hypertension or elderly patients with mild field loss and low IOP levels**¹⁹-²³ [I,D]. (See FC VI)

In most Western countries approximately half of patients with manifest glaucoma are undiagnosed²⁴-²⁷, and glaucoma is often diagnosed late⁶. Improved case finding and possibly screening of high risk groups are necessary to allow diagnosis at earlier disease stages. Screening options for high risk groups should be evaluated. To discover and treat those at risk of losing functionally significant vision is a more important goal for effective glaucoma management than widespread treatment of patients with ocular hypertension. Currently, the only approach proven to be efficient in preserving visual function is lowering IOP²⁸-³¹ (See Ch. Introduction and FC VI to XI) [I,A]. Other possible treatment areas have been investigated, including ocular blood flow and neuroprotection. There are experimental as well population based studies indicating that perfusion pressure may be relevant in glaucoma³¹-³⁷ but very difficult to measure³⁸ a specific glaucoma phenotype characterised by vascular dysregulation has been described³⁹. An increase of IOP will lead to a reduction of perfusion pressure. Blood pressure levels may also be important in glaucoma³⁷. However, there is no conclusive evidence to support the idea that perfusion pressure can be increased by manipulating blood pressure or ocular blood flow in glaucoma patients. Neuroprotection can be defined as a “therapeutic approach” aiming to directly prevent, hinder and, in some cases, reverse neuronal cell damage. Since glaucoma patients can continue deteriorating in spite of an apparently well controlled IOP, the need for effective non-IOP related treatments is widely acknowledged. Several compounds have been shown to be neuroprotective in animal models of experimental glaucoma³⁹-⁴³. So far, no compound has reached a sufficient level of evidence to be considered as a neuroprotectant in humans. A large long-term randomized trial using a neuroprotective agent, memantine, was analysed several years ago, but with negative results. A more recent study claiming that topical brimonidine might haven neuro-protective properties in glaucoma patients, has been questioned in a systematic review on neuroprotection in glaucoma⁴⁴,⁴⁵.

**In most western countries, approximately half of patients with manifest glaucoma are undiagnosed²⁴-²⁷.**

3.2 - TARGET IOP AND QUALITY OF LIFE

3.2.1 Target Intraocular Pressure (Target IOP)

Therapy in glaucoma management aims to lower IOP to slow the rate of visual field deterioration.

Target IOP is the upper limit of the IOP estimated to be compatible with a rate of progression sufficiently slow to maintain vision-related quality of life in the expected lifetime of the patient. It should be re-evaluated regularly and, additionally, when progression of disease is identified or when ocular or systemic comorbidities develop [II,D].

There is no single Target IOP level that is appropriate for every patient, so the Target IOP needs to be estimated separately for each eye of every patient (See FC IX and X) [II,D].

---

**FC IX - Considerations on Target IOP**

- Advanced initial glaucoma damage
- Fast rate of progression
- Long life expectancy
- Adverse consequences of intervention
- Additional risk factors
- Status of other eye
- Target IOP
- Patient preferences

The treatment target is a compromise between reducing the risk of symptomatic vision loss and the consequences of therapy. Patient preferences should be taken into account.
Factors to consider when setting the Target IOP include\textsuperscript{9, 28, 46} [II,D]:

- Stage of glaucoma
  - The greater the pre-existing glaucoma damage, the lower the Target IOP should be
- IOP level before treatment
  - The lower the untreated IOP levels, the lower the Target IOP should be
- Age and life expectancy
  - Whilst younger age implies greater life expectancy and, therefore, a lower Target IOP, older age is a risk factor for more rapid progression
- Rate of progression during follow-up
  - The faster the rate of progression, the lower the Target IOP should be
- The presence of other risk factors, e.g., exfoliation syndrome
- The side effects and risks of treatment
- Patient preference

When taking the IOP reading, it is advisable to consider CCT [I,C]. Several clinical studies have identified that worse initial visual field loss is the most important predictor of blindness from glaucoma\textsuperscript{7, 47-49}. When considering the Target IOP for one eye, the vision status of the other eye should be taken into account. In a newly-diagnosed patient, the rate of progression is unknown and Target IOP is based on risk factors for progression (See Ch. 2.2.2.1). After sufficient follow-up and with sufficient visual field tests to reliably determine the progression status, usually 2-3 years, the importance of the risk factors for decision-making decreases and importance of the measured rate of progression increases; the rate of progression should be used to adjust the Target IOP, taking into account IOP levels over the observation period, life expectancy, and current levels of visual function damage (See FC X)\textsuperscript{22}. 
3.2.1.1 Setting the Target IOP

There is little evidence base to support any particular algorithm to set the Target IOP, but data from clinical trials may be used as a guide. As clinical trials have shown that progression occurs in eyes that have an IOP within the statistically normal range (<21 mmHg), older recommendations that treated IOP should be simply within the statistically normal range are no longer regarded as sufficiently ambitious.

In newly diagnosed patients, the Target IOP is initially determined according to stage of disease and the starting IOP, with the treatment goal being a specific IOP level or a percentage reduction, whichever is the lower[^6] [II,D]. For instance, in early glaucoma, an IOP of <21 mmHg with a reduction of at least 20% may be sufficient. In moderate glaucoma, an IOP <18 mmHg with a reduction of at least 30% may be required [II,D]. Lower Target pressures may be needed in more advanced disease [I,D]. The Target IOP based on stage of disease and IOP then needs to be refined according to the presence of other risk factors, expected longevity of the patient, the burden of therapy and the patient preferences (See FC X[^6] [II,D]).

---

**FC X - Setting the Target IOP**

The above factors need to be considered as a whole in deciding the individual target pressure required.

* Consider central corneal thickness.
3.2.1.2 Achieving the Target IOP

Initial therapy may be with topical medication or laser trabeculoplasty [I,A]. The principles of adjusting therapy to achieve treatment targets are shown in Flow Charts IX - X - XI. To minimize side effects, the least amount of medication required to achieve the desired therapeutic response should be given. If a patient fails to attain the Target IOP during follow-up, and additional therapy is being considered, then the Target IOP should be reaffirmed to ensure that it is still appropriate [II,D].

**FC XI - Adjustment of Target IOP**

Determine Individualized Target IOP

- Prescribe treatment accordingly and re-evaluate for progression

  - Progression
    - Consider Lower Target IOP
  - Stable
    - Follow-up 6 months
      - Progression
      - Stable

  Target IOP reached
  - Re-evaluate after 6-12 months

Target IOP not reached
  - Consider accepting higher target IOP
  - Re-evaluate
3.2.1.3 Re-evaluating Target IOP

If the visual field is worsening at a rate that may threaten Quality of Life during the patient’s expected lifetime, then the Target IOP, if previously met, should be lowered; a further 20% reduction has been shown to be effective. If the Target IOP had not previously been met, then additional therapy should be considered, in consultation with the patient, weighing the risks and benefits of the additional intervention (See FC XI) [I,D].

If there are sufficient visual fields to judge the rate of progression, and this rate is sufficiently slow not to impact on the patient’s quality of life, then the Target IOP may be revised upward if the Target IOP has not been met or if the patient is on excessive therapy or is experiencing side effects [II,D].

If there are insufficient visual fields to judge the rate of progression and the Target IOP has not been met, then additional therapy should be considered, as above [II,D].
3.3 - ANTIGLAUCOMA DRUGS

Several prospective randomized multi-centre controlled clinical studies have clearly established the benefits of IOP reduction in managing POAG at various stages of the disease whether of the ‘high pressure’ or ‘normal pressure’ variety as well as reducing the conversion of OHT to POAG.\textsuperscript{10,18,28,58,56} I,A.

Most forms of open-angle glaucoma and many types of chronic angle-closure glaucoma are initially treated with topical and occasionally orally administrated agents that act either on the reduction of aqueous humour production or enhancement of the aqueous outflow or on both. An uncommon exception to initiating treatment with medical therapy is for eyes with a very high level of IOP at presentation causing an immediate threat to sight. Additionally many forms of childhood glaucoma are managed with early surgery I,D. Although acute angle closure with or without glaucoma needs rapid laser or incisional surgery, medical treatment usually will be initiated as a first step in most cases. Laser treatment may be a suitable first option for patients with known intolerance or allergy to topical agents or suspected poor compliance I,A.

When initially selecting medical therapy it is important to consider some relevant patient’s characteristics as well as features related to the drug (See FC XII and XIII).
3.3.1. Start with Monotherapy

It is recommended to initiate the treatment with monotherapy (See FC XIII - XIV) [I,D]. Treatment is considered “effective” when the achieved IOP reduction on treatment is comparable to the published average range for that drug in a similar population. According to a meta-analysis of randomised controlled trials, the highest reduction of IOP is obtained with prostaglandins, followed by non-selective b-blockers, alpha-adrenergic agonists, selective b-blockers and at last topical carbonic anhydrase inhibitors57.

It should be noted, however, that treatment effects depend on baseline IOP, with larger reductions in patients with higher pre-treatment pressure levels. At low IOP values medical and/or laser therapy have smaller effect on IOP. Therefore, when evaluating the efficacy of a therapy or a drug it is important to consider the pre-treatment baseline IOP58.

If this initial therapy reduces IOP to the target and is well tolerated, therapy can be left unchanged, but the patient needs to be monitored with regular checking of endpoints [I,D].

**FC XIV - Therapeutical Algorithm in Glaucoma Topical Therapy**

- **FIRST CHOICE MONOTHERAPY**
  - PGAs, -Blockers, CAIs, -agonists, others
- If well tolerated and effective on IOP:
  - Target IOP not reached
    - Add 2nd drug
- If not tolerated or not effective on IOP:
  - Target IOP not reached
    - Switch monotherapy to laser
- PERIODICALLY VERIFY ENDPOINTS:
  - Visual field
  - Optic disc
  - IOP

If poor response to several different medications, consider non-compliance

Treatment Principles and Options

3.3.1.1 Switch to Another Monotherapy

If the initial therapy does not seem effective, with the target pressure not being reached, or the drug is not tolerated, one should switch to another monotherapy rather than adding a second drug [II,D]. This applies also to prostaglandin analogues, (PGA) when used as first choice. As there are non-responders to certain PG analogues the switch to another PGA or another class of monotherapy might be of benefit [II,D]. Laser therapy may also be a therapeutical option (See FC XIII) [I,A].

3.3.1.2 Add Second Drug / Combination Therapy

If the first choice monotherapy is well tolerated and has effective IOP lowering but has not succeeded in reaching the target pressure, the addition of a second drug should be considered [II,D]. While individualizing adjunctive therapy, issues to consider in selecting an adjunctive agent include additive efficacy, safety, frequency of dosing and cost. It is recommended to combine agents with different modes of action, one that affects production of aqueous humour and another that influences outflow [II,D]. In general, treatment with a combination of agents of different classes is associated with superior IOP lowering efficacy compared to each of the components used alone [I,A] (see Tables 3.1-3.2). However poly-drug regimens for glaucoma pose several important clinical challenges: multiple topical treatments may jeopardize adherence59,60, result in reduced efficacy through wash-out of earlier medications with later medications61,62 and increase exposure to preservatives63, 64.

Therefore, fixed combination therapy, when available, should be preferable to two separate instillations of agents [I, B]. Currently, all fixed combinations available in Europe contain a beta-blocker. However, beta-blocking agents can be associated with systemic side effects and need to be used cautiously in patients with serious concomitant cardiopulmonary diseases. It is therefore mandatory to exclude patients with these contra-indications before prescribing fixed combinations [I,D]. It is not recommended to combine two bottles of fixed combinations as both will contain a -blocker and double the amount of this active drug with the risk of more systemic side effects [I,D]. On the other hand, fixed combinations containing timolol may be associated with a better local tolerability in some patients, though data are limited.55

Fixed combinations usually have clinical equivalence to unfixed combinations; slight differences in IOP-lowering efficacy may be seen in some cases.66,67 Occasionally IOP-lowering agents are available as fixed combinations in some countries and are in development in others. A new fixed combination without a -blocker, containing a carbonic anhydrase inhibitor (brinzolamide 1.0%) and an alpha 2 adrenergic receptor agonist (brimonidine tartrate 0.2%) has been recently approved by the FDA and submitted to EMEA but is not yet widely available. Also, a new fixed combination of tafluprost 0.0015% and timolol 0.5% has been submitted to EMEA.

Combination therapy, either as poly-drug regime or as fixed combination, is not recommended as first-line treatment [II,D]. However, in selected cases, such as advanced glaucoma and/or very high levels of IOP, the requested IOP reduction
may exceed the efficacy range that can be expected by a single agent. Therefore, although the standard treatment algorithm remains unchanged, the time interval between incremental therapeutic steps may be decreased, combination therapy, fixed or unfixed, can be adopted more quickly than usual or even immediately [II,D]. If combination therapy fails to lower IOP sufficiently, one can either substitute the second drug or add a third medication to the fixed combination. At this stage however laser or incisional surgery, if possible, should be considered [II,D].

3.3.2 The Effect on IOP

The pre-post IOP graph shown below is a useful tool to show the IOP changes induced by treatment and its use should be encouraged in publications.

![Graph showing IOP changes](image)

**Figure 3.2.** The Pre - Post IOP Graph. A simple graph can be used to show the IOP lowering effect. Different shapes/colours can be used to show different patient series or different observation times. Vertical and horizontal lines show respectively Pre and Post Treatment IOP levels of interest, here placed as examples at 15 and 21 mmHg. Areas of desired effect under the oblique “no effect” line can thus be defined.

Treatment “A” blue dots: eye n 1 lies on the “no effect” line. Eyes n 2 and n 3 both show a large effect, with only the former below the 15 mmHg line. Eye n 4 shows a sizeable decrease of IOP but the absolute level is still >21 mmHg.

Treatment “B” red dots. Eyes n 1 and n 2 show a slight increase and a slight decrease of IOP, respectively; eye n 3 shows a very large effect, as well as eye n 4, both remaining below the 15 mmHg line.
REMEMBER: [I,D]

* Assess each eye individually when deciding the most appropriate therapy.
* It is essential to involve patients as informed partners in decisions regarding the management of their condition.
* The least amount of medication (and consequent inconvenience, costs and side effects) to achieve the therapeutic response should be a consistent goal.
* A therapeutic medical trial on one eye first can be useful to determine the IOP lowering efficacy, although not always logistically feasible or advisable (e.g., very high IOP or advanced disease).
* Usually there is no need to start treatment until all baseline diagnostic data are collected, unless the IOP is very high and there is severe damage.
* After diagnosis it is advisable to measure untreated IOP more than once before initiating IOP-lowering treatment.

The following pages outline the most frequently used anti-glaucoma medications, and emphasize their mode of action, dosage and side effects. A complete list of all possible medications is beyond the scope of the Guidelines.
Treatment Principles and Options

Antiglaucoma drugs have been available since 1875. The following diagram shows the chronology of the introduction of topical intraocular pressure-lowering medications (Fig. 3.3).

Systemic carbonic anhydrase inhibitors are available since 1955

**Figure 3.3.** IOP lowering molecules and year of first clinical use. FC: fixed combination. In black: monotherapy.

There are six classes of topical antiglaucoma drugs. The following tables contain only the most common classes and compounds, their most common side effects and contraindications. They are listed in order of first and second line drugs. The seventh category is systemically administered osmotics. The use of some compounds like epinephrine and dipivefrin has decreased significantly since drugs with better efficacy and fewer side effects became available. The text should be considered as a general guide, and cannot be all-inclusive.

3.3.4.1 Prostaglandin Analogues

Since their development in the 1990s, prostaglandin derivatives (latanoprost, travoprost, bimatoprost and tafluprost) (Table 3.3) have progressively replaced beta-blockers as first-choice/first line therapy. This is mainly because they are the most effective IOP-lowering agents,54 lack relevant systemic side effects and require just once-daily administration. Recently, a number of latanoprost generics as well as preservative-free and BAC-free prostaglandin formulations have entered the glaucoma market. The primary mechanism of action of prostaglandins is to increase uveoscleral outflow, reducing IOP by 25%-35%. Reduction of IOP starts approximately 2-4 h after the first administration, with the peak effect within approximately 8-12 h. Thus, IOP measurements taken in the morning represent the peak effect of the prostaglandin analogues for patients administering the drug in the evening. Clinical trials that measured 24-hour IOP suggested that evening administration is generally preferable because it gave a better circadian IOP profile68-70 III, B]. These studies also reported that eyes treated with PG derivatives have reduced short-term IOP variability as compared to eyes treated with other classes of drugs11. Maximum IOP lowering is often achieved 3-5 weeks from commencement of treatment. Differences among drugs within this class in the capability of reducing IOP did not exceed 1 mmHg72. When combined with most of the other antiglaucoma drug classes, prostaglandin agents provide additive IOP lowering. Non-responders to prostaglandin analogues (e.g. eyes with IOP reductions of less than 10% or 15% from baseline) are fewer than 10%73,74. Some reports indicate that poor responders to one prostaglandin agent might respond to another agent within the same class75,76. Conjunctival hyperemia, generally mild, is a common finding with slight difference in frequency and level among agents within this drug class. It usually decreases over time. Other PG side effects are reported in Table 3.3. Details on the mode of action, IOP lowering effect, contraindications and side effects of other first line drugs (-blockers, carbonic anhydrase inhibitors, alpha-2 selective adrenergic agonists) and second line drugs are listed in Tables 3.5-3.10.
3.3.5 Local Toxicity of Topical IOP - Lowering Treatment. The Role of Preservatives

Long-term topical glaucoma medications may cause and/or exacerbate pre-existing ocular surface disease (OSD), such as dry eye, meibomian gland dysfunction and chronic allergy,\(^7\) which, in glaucoma patients, has a much higher prevalence than in the general population.\(^3,4,7\) OSD may follow chronic use of antiglaucoma medication and/or the preservative benzalkonium chloride (BAC). BAC, a quaternary ammonium compound is the most frequently used preservative agent in eye drops and its usage correlates well with the signs and symptoms of OSD.\(^3,4,7\) Such signs and symptoms can diminish if BAC-preserved drops are substituted with non-preserved drops.\(^3\) An unwanted effect of BAC is a reduction in the success rate of filtering surgery.\(^3,4,7\) In vitro studies suggest that alternative preservatives are significantly less toxic than BAC.\(^3,4,7\)

Other therapeutic possibilities are the use of preservative-free or BAC-free medication, decreasing the number of preserved eyedrops i.e. by using fixed combinations; treating the ocular surface with unpreserved tear substitutes and performing earlier laser or surgery. When considering OSD four factors have to be considered: the active compound, the specific preservative, the ability of the patient to use single-dose preparations and the patient’s ocular surface.

The European Medicines Agency (EMEA) has suggested that the use of preservatives should be avoided in “patients who do not tolerate eye drops with preservatives” and in those on long-term treatment, or to use “concentration at the minimum level consistent with satisfactory antimicrobial function in each individual preparation”, with a specific indication to avoid mercury containing preparations.\(^3\)

Not all patients are sensitive to preservatives and not all the local side effects observed with topical antiglaucoma medications are induced by preservatives. Particular attention should be paid to glaucoma patients with pre-existing OSD or to those developing dry eye or ocular irritation over time. This can be done by careful assessment of redness of the eyelid margin, positive corneal and conjunctival fluorescein staining or reduced tear break-up time.\(^1,4\)

3.3.6 Generic IOP - Lowering Topical Medications

By definition a generic drug is identical to a brand name drug in dosage, strength, route of administration, performance characteristics and intended use. For the purposes of drug approval, the interchangeability of a generic drug and the corresponding brand-name drug is based on the criterion of “essential similarity”. In ophthalmology this concept is problematic, because it is difficult to prove “essential similarity” in clinical studies. With systemic drugs bioequivalence studies are performed using blood samples to determine whether the plasma concentration within certain limits equals the branded drug. With topical eye drops such studies obviously cannot be performed.

No clinical studies are usually required for generic approval in ophthalmology, and a 10% difference between the concentration of the active principle between the generic and the branded products is considered acceptable. Whereas the active principle is assumed to be equal, the adjuvants can vary considerably. This is a critical issue.
Treatment Principles and Options

because different adjuvants may alter the viscosity, osmolarity and pH of the eye drops and therefore have an impact on both tolerability and corneal penetration. Nevertheless anti-glaucoma generics drugs are currently prescribed at a large scale, as many drugs are becoming off patent. For latanoprost, the generic share is more than 65% in most European countries. To which degree these generics are similar in efficacy and tolerability is not well studied. Only few clinical studies have compared the effect of generic and brand IOP lowering medications in glaucoma, with variable results depending on the type of generic drug. Other studies have shown a difference between the branded and the generic preparations concerning the size and amount of drops in the bottle, the structure of the bottle and the bottle tips. Safety issues with corneal epithelial disorders have also been described with generics, due to an additional stabiliser compound. When switching patients from branded to generic drugs, the IOP should be closely monitored.

3.3.7 Dietary Supplementation and Glaucoma

Although there is no clinical evidence for clinical benefits arising from the use of dietary supplements in glaucoma, a recent survey has found that 1 in 9 glaucoma patients were using complementary and alternative medicine (CAM). Most were using herbal medicines (34.5%), dietary modifications (22.7%) or dietary supplements (18.8%). Based on the fact that some glaucoma patients continue to progress at low IOPs, there is much room for hypotheses, preclinical experiments, clinical trials and speculation. Some data from experimental studies suggest that dietary supplementation may reduce oxidative stress, or that the omega 3 polyunsaturated fatty acids (PUFAs) decrease IOP in rats. At the present time there is no robust interventional dietary supplementation study demonstrating the positive effect of such a treatment in glaucoma patients. Observational studies have suggested a reduced risk for glaucoma with higher fruit and vegetable intake or higher omega 3 PUFAs consumption in selected populations. Conversely there is evidence that some of these compounds may cause harm, such as an increased intake of magnesium associated with a higher incidence of glaucoma.

**DIETARY SUPPLEMENTATION**
At the present time there is no robust interventional dietary supplementation study demonstrating the positive effect of such a treatment in glaucoma patients.

3.3.8 Management of Glaucoma During Pregnancy and Breast-feeding

Pregnancy-related changes in ocular physiology can influence IOP as well as the reliability of its measurements. Changes in hormonal levels, are thought to induce an IOP-lowering effect that increases throughout pregnancy (but particularly during the 24th-30th week) and can last for months after delivery. The most sensitive period is the first trimester due to concerns relating teratogenicity,
as the majority of IOP-lowering medications are within class C (See Table 3.10) meaning that adverse effects have been seen in animals or that there are no human or animal data (See Table 3.11). Therefore, for a woman with glaucoma who is of child bearing age, who might wish to conceive, the treatment strategy during pregnancy should be discussed [I,D]. The patient should be instructed to inform the ophthalmologist when pregnancy occurs. The potential risks to the fetus (and neonate) of continuing anti-glaucoma medications must be balanced against the risk of vision loss in the mother [I,D]. As IOP levels generally decrease during pregnancy, temporary treatment discontinuation can be considered under strict follow-up in some patients. However, if continuation of treatment is mandated, the lowest effective dosage of medication should be used. Moreover, systemic absorption should be reduced by punctal occlusion, eyelid closure, and blotting excess drops away during administration [I,D].

Drugs are classified in Classes A to X for use during pregnancy based on a hierarchy of estimated fetal risk (See Tables 3.10-3.11) [10]. Although very similar, some countries (e.g., Sweden, Australia, the Netherlands, Switzerland, and Denmark) have their own classification systems.

### Table 3.10 Drug classification for use of drugs during pregnancy

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class A</td>
<td>Controlled studies show no risk. Adequate well-controlled studies in pregnant women have failed to demonstrate risk to the foetus</td>
</tr>
<tr>
<td>Class B</td>
<td>No evidence of risk in humans. Either animal findings show risk, but human findings do not or, if no adequate human studies have been done, animal findings are negative</td>
</tr>
<tr>
<td>Class C</td>
<td>Risk cannot be ruled out. Human studies are lacking, and animal studies are either positive for foetal risk or lacking as well. However, potential benefits may justify the potential risk</td>
</tr>
<tr>
<td>Class D</td>
<td>Positive evidence of risk. Investigational or post-marketing data show risk to the foetus. Nevertheless, potential benefits may outweigh the potential risk</td>
</tr>
<tr>
<td>Class X</td>
<td>Contraindicated in pregnancy. Studies in animals or human, or investigational or post-marketing reports, have shown foetal risk which clearly outweighs any possible benefit to the patient</td>
</tr>
</tbody>
</table>

Treatment Principles and Options

Brimonidine is a Class B medication: however, there are reports of central nervous system side effects in young children. The ability of this drug to cross the placenta and the lack of well-controlled human studies during pregnancy do not allow ruling out possible adverse effects on the fetus. Betaxolol is also in class B and is characterized by a larger volume of distribution in the fetal circulation, high binding to proteins and therefore fewer central nervous systemic effects on the fetus. Timolol although class C, is available in low dosage (0.1%), in slow-release preparations which can be used once daily. Although these formulations are thought to reduce systemic absorption, strong evidence to support this is still lacking. Once-a-day timolol 0.1% gel may be a valid option if a beta-blocker is considered [I,D]. Prostaglandin-analogues should be considered with caution because of the theoretical risk of increased uterine contractility in pregnancy. If premature contractions appear PG should be discontinued immediately [I,D].

There have been no reports on any fetal complications related to the use of topical carbonic anhydrase inhibitors in humans, but animal studies have shown that high systemic doses, are associated with low weight offspring (Manufacturer’s Information: Azopt product monograph. Fort Worth, Texas, Alcon Ophthalmics, 1998 Manufacturer’s Information: Trusopt product monograph. West Point, Pennsylvania, Merck Inc., 1999). At clinically used concentrations, BAC has no known impact on the fetus [I,D].

Table 3.11 summarizes known adverse effects of anti-glaucoma drugs during pregnancy and breast-feeding.

Although results from animal studies are worrisome, the overall level of evidence for the risk of giving anti-glaucoma drugs to pregnant women is low. Laser trabeculoplasty is considered to be a safe alternative except in patients with angle dysgenesis. However, IOP lowering success is lower in younger patients, such as in women of childbearing age [I,D].

Laser cyclodestruction, in spite of having been suggested as a valid option should be considered with caution because of risk of sight-threatening complications [I,D].

If surgery is planned, there are a number of considerations to be made. A supine position should be avoided [I,D]. For intervention under local anesthesia, topical, subconjunctival or retrobulbar, lidocaine is considered to be a safe option [I,D]. The use of anti-metabolites is strictly contraindicated, due to the mutagenic related risk. Depending on previous ocular surgeries and the age of patient, filtering surgery, including tube shunt implantation, can be considered [II,D].

Topical prednisolone and erythromycin have been shown to cross the placenta to a lesser extent than other medications of their classes, and can therefore be chosen as postoperative medication [I,D].

Special attention should be paid also during breast-feeding. Carbonic anhydrase inhibitors and beta-blockers may be used in nursing mothers as suggested by the American Academy of Pediatricians. These are also the first line choices in infants with congenital glaucoma when medical therapy is being considered. Fixed combinations are all class C. Prescribing physicians should separately consider each of the drugs involved [I,D].

**NOTE:** There is a lack of well-controlled human studies during pregnancy. Therefore it is not possible to accurately determine the real incidence of the stated adverse effects, or to exclude the existence of any additional unforeseen adverse effects on the fetus.

### 3.3.8 Neuroprotection and Glaucoma Treatment

Neuroprotection can be defined as a “therapeutic approach” aiming to directly prevent or significantly hinder neuronal cell damage. Since glaucoma patients can continue deteriorating in spite of an apparently well controlled IOP, the need for effective non-IOP related treatments is widely acknowledged. Several compounds have been neuroprotectant in preclinical studies\(^{19}\). Only two have reached large scale clinical trials: a large long-term RCT using an NMDA antagonist, memantine, was analysed in 2008 with negative results. More recently, the results from a multi-center RCT of adults with low-pressure glaucoma (Low-pressure Glaucoma Treatment Study, LoGTS) has been claimed to show that brimonidine may have neuroprotective properties in comparison to Timolol\(^{44}\). No direct comparison has been done with other substances such as PG. However, the authors of the study and a systematic literature review have (both?) suggested that more substantial evidence is needed\(^{21,122}\).
3.3.9 Practical Considerations Related to Topical Medical Treatment

The majority of topically applied drugs, particularly if lipophilic, penetrate the eye via the cornea, in a lesser amount via the conjunctiva and thereafter the sclera. On average, the total tear film volume is around 7 μl and the rate of tear film turnover is approximately 15% (±1 μl) per minute but can double (washout effect) after the application of a topical drop with a volume estimated at 30-50 μl\textsuperscript{23}. Although the cul-de-sac and tear film compartment can expand transiently after instillation of a drop it still cannot accommodate this whole volume and less than 5% manages to enter the eye; the rest will run down the cheek or will be drained through the nasolacrimal duct where an individually variable systemic absorption takes place through the highly vascularised nasal mucosa\textsuperscript{24}.

Once the medication is instilled into the conjunctival sac, the spontaneous tear flow will cause complete washout within 5 minutes. The washout effect depends not only on the increased tear fluid turnover, but also on the addition of a second drop within a short period. Therefore when poly-drug regimen is used, a minimum time span between different drops should be respected. When two drugs are instilled only 30 seconds apart, almost 50% of the first drug will be washed out. The recommended delay between drops is 5 minutes with a washout effect of less than 15%\textsuperscript{61,62} [I,B].

Blinking also may influence washout and allow only 15% of a topically applied drug to remain in the eye approximately five minutes after instillation. As drugs absorbed through the highly vascularised nasal mucosa avoid hepatic first-pass metabolism this might lead to systemic side effects. The instillation of one drop of timolol 0.5% for example may lead to a serum concentration of timolol that equals the intake of an oral 10 mg non-selective beta-blocker\textsuperscript{125}.

There is no evidence that nasolacrimal duct obstruction may increase the efficacy of a topical drug\textsuperscript{126} however it may reduce systemic side effects particularly from beta-blockers by minimizing the drainage into the highly vascularised nasopharyngeal mucosa\textsuperscript{50,127,128} [I,D].

Patients should be advised to shake the bottle before use as micro-suspensions tend to settle to the bottom of the bottle leaving the vehicle at the surface. Thus, patients may be simply applying mainly vehicle to the eye, rather than the active drug ingredient [I,D].
GENERAL RECOMMENDATIONS [I,D]:

- Monotherapy is the first choice when initiating therapy
- Baseline IOP should be considered when evaluating the efficacy of a therapy
- Fixed Combination therapy should be considered when patients fail to achieve their individualized intraocular pressure (IOP) targets with monotherapy
- The prescription of more than two bottles of IOP lowering eye drops for simultaneous use should be avoided as it can lead to noncompliance
- Fixed combination preparations may be preferable to the use of separate instillation of two agents
- However Fixed Combination are not first-line medications and they are only indicated in patients who need adjunctive therapy, when IOP is not sufficiently controlled by one single agent
- Ocular surface should be evaluated and considered in clinical management of glaucoma patients. In case of ocular surface disease, preservative-free formulations should be considered
- Generic drops can differ from brand drops and it may be necessary to monitor patients more closely after switching
- During pregnancy, the potential risks of continuing anti-glaucoma medications to the fetus (and neonate) must be balanced against the risk of vision loss in the mother

See FC IX to XIII
Treatment Principles and Options

3.4 - ADHERENCE, COMPLIANCE AND PERSISTENCE IN GLAUCOMA

Glaucoma is a chronic progressive disease that requires continuous long-term cooperation of the patient with the glaucoma management proposed by the doctor.

3.4.1 Terminology

The commonly used term “compliance” has been increasingly replaced in recent times by the term “adherence”. Both are defined as the “cooperation of the patient with the recommendations given by the doctor”. However, the former is more passive (“I am taking the medication”), while the latter implies the active part of the patient in the process (“I am taking the medication exactly as you told me”). “Persistence” is defined as the length of time during which the patient is taking the medication as prescribed.

Finally three terms should be mentioned:

- “White coat compliance” means that the patient’s adherence rises a week before the consultation and drops quickly afterwards.
- “Dyscompliance” is used when physical problems of a patient, like arthritis, lead to difficulties in correctly applying a therapy.
- “Alliance” is a special form of adherence meaning that the people around the patient ensure the correct application of the medication.

3.4.2 Measured Adherence

Despite easier medication schemes (for example drugs which require application once-daily) and more information for the patients about the disease, the rate of non-adherence has remained almost the same over the last 25 years; between 30%-70%.

It is important to mention that the patients themselves overestimate their adherence and persistence rate (GAPS).

3.4.3 Factors Associated with Non-Adherence

Four groups of factors encountered as common obstacles to glaucoma medication adherence have been described:

- Situational / environmental (for example a major event in the patients life, unsteady life-style with many travels)
- Medication (for example costs of the drugs, side effects, complicated dosing regimen)
- Patients (for example comorbidity, poor understanding of the disease)
- Provider (for example lacking communication with the doctor)

Other influencing factors:
- Gender (men are more likely to be non adherent)
- Stage of the disease (patients with a less advanced disease tend to be less adherent)
3.4.4 Types of Non-Adherence

Every patient is different and there are several types of non-adherence:\textsuperscript{134}

- Failure to take the medication as prescribed (including under- and overdosing, inadequate doses and wrong timing of dosages)
- Failure to use the correct medication (including the application of the wrong medication or the self administration of not prescribed drugs)
- Failure to apply the medication correctly (including incorrect self administration of the medication)
- Failure to continue applying the medication (including problems with side-effects, issue of costs and missed refills)

3.4.5 Improving Adherence

There are different ways for improving the adherence of patients. The most important measures are informing the patient about his/her disease and finding a therapeutic regimen which fits into the patient’s life-style\textsuperscript{135} \[1, D\]. Other factors which should improve adherence \[1, D\]:

- The therapy should be simple i.e. not more than two bottles and an application not more than twice a day
- The patient should be instructed how to apply the drops correctly. If necessary, hints reminders should be given like a daily routine which the patient can connect to the application of the drops. If a patient has physical problems applying the drops as arthritis of the fingers, the therapy should be adjusted accordingly or switched to laser/surgery
- The doctor should inquire at every visit if the patient has side effects of the medication and switch if necessary. A patient who complains about side effects is usually not adherent to therapy.

The patient’s cooperation, described as adherence and persistence, with the prescribed glaucoma management is mandatory to obtain effective IOP lowering and to prevent glaucoma progression. No drug can work unless it is taken.
3.5 - LASER SURGERY

3.5.1 Laser Iridotomy\(^{36-39}\)

**Indications:** [I,C]
Clinically relevant or suspected pupillary block.
Potential prevention of acute and chronic angle closure (See FC X and XI).

**Preoperative preparation:**
To reduce iris thickness and facilitate perforation instil 1 drop of Pilocarpine 2%-4% [I,D].
If the cornea is edematous, like acute angle closure, use topical glycerin 10% if available,
systemic acetazolamide, intravenous mannitol or oral hyperosmotic agents (See FC XI).
For prevention of IOP spikes use topical alpha 2 agonist 1 hour prior to the procedure
and immediately afterwards [I,B].

**Procedure:**
After instillation of topical anesthetic a contact lens with contact lens fluid is placed
onto the cornea. The lens keeps the eyelids open, stabilizes the eye, provides additional
magnification, focuses the laser beam and acts as a heat sink.
Lenses used are: Abraham (+66 diopters), Wise (+103 diopters) or CGI©LASAG CH lens.
Iridotomy site [II,D] is usually chosen in the superior quadrants of the iris well covered
by the upper eyelid (to reduce visual symptoms), in a thin looking area or an iris crypt.
Whole thickness perforation of the iris is assumed when pigment, mixed with aqueous,
flows from the posterior into the anterior chamber. Once a full thickness hole has
been made, it should be enlarged horizontally to achieve an adequate size. Iridotomy
size [II,D] should be sufficient for patency inspite of iris oedema, pigment epithelial
proliferation and pupil dilation. Transillumination through the iridotomy is not a reliable
indicator of success [II,D].

**Lasers parameters for Nd:YAG laser iridotomy**

<table>
<thead>
<tr>
<th>Power</th>
<th>1-6 mJ</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spot size</td>
<td>50-70 µm (constant for each laser model)</td>
</tr>
<tr>
<td>Pulses per burst</td>
<td>1-3</td>
</tr>
</tbody>
</table>
| Recommendations | Set defocus to zero
Focuss the beam within the iris stroma rather than on the surface of the iris
Avoid any apparent iris vessels
Use the least amount of energy that is effective\(^{39}\)
Lense capsule damage is possible above 2 mJ energy
With most Lasers less than 5 mJ per pulse is required |

* Pretreatment with argon laser to minimize bleeding by coagulating iris vessels is optional (spot size 400 µm, duration 0.2 sec, energy approximately 200-300 mW).
In case of thick dark irides, to reduce total Nd:YAG energy, pretreatment with argon laser in 2 stages may be considered. In the first stage a low power argon of 90-250 mW, duration 0.05 sec, spot size 50mm is applied, followed by the high power argon of 700 mW, duration 0.1 sec, spot size 50 mm to create a punched-out crater appearance. Laser iridotomy is completed with Nd:YAG laser.

**Laser parameters for continuous-wave Argon laser iridotomy**

When no Nd:YAG laser is available, Argon laser may be used. Laser parameters should be individualized to each patient and adjusted appropriately during the procedure.

The following parameters are suggested:

<table>
<thead>
<tr>
<th>Medium brown irides</th>

| Thick, dark brown irides (chipping technique) |
| Spots size | 50 μm |
| Exposure time | 0.02 sec |
| Power       | 1500 mW |
Treatment Principles and Options

Complications:

∞ Intraoperative complications

Bleeding from the iridotomy site; this can usually be stopped by gentle pressure applied to the eye with the contact lens. With the argon laser corneal epithelial and/or endothelial burns may develop.

∞ Postoperative

Visual disturbances occur in 6-12% (glare, blurring, ghost images, halo, crescent) are less likely to occur when the iridotomy is completely covered by the eyelid. Transient elevation of the IOP is the most common complication in the early period. Elevation of IOP at 1 hour after iridotomy occurs in approximately 10% of primary angle closure suspect eyes. Acute and (chronic) rise in IOP is more likely to occur in eyes with peripheral anterior synechiae in whom the small amount of trabecular meshwork not closed is likely to have compromised outflow function (and is secondarily closed by the iris pigment and tissue generated by the iridotomy). Postoperative inflammation is transient and mild, rarely resulting in posterior synechiae. Closure of the iridotomy may occur during the first few weeks after the procedure, due to accumulation of debris and pigment granules. Rare complications include sterile hypopyon, cystoid macular oedema, retinal haemorrhages and malignant glaucoma.

Postoperative management:

Check the IOP after 1-3 hours [II,D].

Check the angle regularly with gonioscopy, and the patency of peripheral iridotomy. If the patency is uncertain check with gonioscopy, reconsider the mechanism, perform ultrasound biomicroscopy (UBM) / anterior segment-optical coherence tomography (AS-OCT) if available and/or repeat the iridotomy.

Retroillumination alone for judging the patency is insufficient.
3.5.2 Laser Trabeculoplasty (LT)\textsuperscript{[47,154]}

Indications: [I,D]
Lowering of IOP in primary open-angle, exfoliative and pigmentary glaucoma, high risk ocular hypertension (OH):

1) When IOP is not satisfactorily controlled with medications (i.e. efficacy, tolerability and adherence)
2) As initial treatment (See FC VII)

Preoperative preparation: [I,B]
For prevention of IOP spikes instillation of topical alpha 2 agonist (apraclonidine 1% or brimonidine) 1 hour prior to the procedure and immediately afterwards is optional. Use topical anesthesia.

Procedure:
Most frequently used lasers are:
- Argon continuous-wave laser (green or blue/green) - argon laser trabeculoplasty (ALT)
- Q-switched, short pulsed, frequency-doubled Nd:YAG (532 nm) laser - selective laser trabeculoplasty (SLT)

Lenses: Goldmann type gonioscopy lens, Ritch trabeculoplasty lens\textsuperscript{©}, CGA\textsuperscript{©}, Meridian, Latina (SLT), Magnaview.

Identify angle landmarks after inspection of all quadrants and place the laser burns between the anterior pigmented trabecular meshwork (TM) and the non-pigmented trabecular meshwork over 180° or 360°.

* Some continue with the power that causes champagne bubble formation

Complications:
- Transient elevation of IOP\textsuperscript{55,156}
- Inflammation (mild)
- Peripheral anterior synechiae (after ALT)
- Corneal endothelial damage in corneas with pigment on endothelium (after SLT)\textsuperscript{157}

Post-operative management: [II,D]
- Check IOP in selected patients (e.g. with advanced glaucomatous damage, one-eyed patients, high pre-laser IOP, exfoliation syndrome, heavily pigmented trabecular meshwork). Use of topical corticosteroids or non-steroidal anti-inflammatory medication 3-4 times daily for 4-7 days.

Effectiveness of laser trabeculoplasty:
- ALT and SLT have the same efficacy\textsuperscript{53,158}.
- Laser trabeculoplasty is initially effective in 80 to 85% of treated eyes with a mean IOP reduction of 20 to 25% (of 6 to 9 mmHg). The effect wears off over time, for both ALT and SLT\textsuperscript{159}.
- LT versus medication: In the Glaucoma Laser Trial, after 7 years of follow-up, patients with ALT had lower IOP (1.2 mmHg) than patients on medical treatment, and no difference in progression of glaucoma\textsuperscript{160}. SLT has shown to decrease IOP to a degree similar to that of prostaglandin analogues after 9 to 12 months follow-up\textsuperscript{161} and appears to be repeatable\textsuperscript{30,31}.

Predictors of efficacy:
- Higher baseline IOP is associated with greater IOP reduction after SLT and ALT\textsuperscript{162,163}.
- The effectiveness of ALT is influenced by the treating surgeon, and success is better when surgeons have more experience in ALT\textsuperscript{163,164}.
- Pigmentation of the trabecular meshwork (TM) is important. ALT is less successful in eyes with no pigmentation of TM. SLT seems to be independent of the pigmentation of TM. Younger subjects (less than 40 years old) usually respond less to ALT\textsuperscript{165}. 

The "Terminology and Guidelines" project was entirely supported by the EGS Foundation
### 3.5.3 Laser Iridoplasty\(^{166,167}\)

**Main Indication: [I,II,D]**
Plateau iris syndrome confirmed by a patent iridotomy; the purpose is to enlarge the peripheral angle approach after iridotomy, to decrease the chance of progressive synechial closure.

**Lasers:**
Different types of continuous wave lasers can be used for photocoagulation, most frequently: argon laser, diode laser (810 nm), and the frequency-doubled Nd:YAG laser (532 nm).

**Preoperative preparation: [I,II,D]**
Instillation of Pilocarpine followed by the same preoperative preparation as for laser trabeculoplasty.
Lens: Abraham (+66 diopters), Wise (+103 diopters), CGI©LASAG CH lens or the central non-mirrored part of the Goldmann lens.

**Contraindications: [I,D]**
Flat anterior chamber
Extensive peripheral anterior synechiae.

**Laser parameters for laser Iridoplasty [II,D]**

<table>
<thead>

</tr>
</tbody>
</table>

**Complications:**
Mild iritis
Corneal endothelial burns
Transitory elevation of IOP
Post-operative synechiae of the pupil
Permanent pupil dilation
Iris atrophy
Non-dilatable pupil

**Post-operative management:**
Topical corticosteroids or non-steroidal anti-inflammatory medication instilled for 4-7 days
Prevention of IOP spikes
3.5.4 Cyclophotocoagulation\textsuperscript{168-170}

**Indications:** [II,D]
When filtration surgery or tubes are likely to fail, have failed, or are not feasible
As an alternative to drainage devices

**Lasers used:**
Diode laser (810 nm); Argon laser
Modes of laser delivery are: trans-scleral, endoscopic and transpupillary

**Trans-scleral cyclophotocoagulation:**
Laser diode cyclophotocoagulation with the G probe is the cyclodestructive procedure of choice because of the reduced incidence of complications compared with other cyclodestructive procedures [I,D].

**Ultrasonic cyclodestruction:**
Ultrasonic circular cyclocoagulation using high-intensity focused ultrasound delivered by a circular miniaturized device was reported as a safe and effective technique to reduce intraocular pressure in patients with refractory glaucoma\textsuperscript{171,172}.

**Technique:** [II,D]

Endoscopic cyclophotocoagulation:  
Endoscopic techniques combined with laser technology allow the photocoagulation of ciliary processes not visible via the transpupillary route. The approach can be limbal or through pars plana. Recently, endoscopic cyclophotocoagulation is most commonly performed in conjunction with cataract surgery in cases with early glaucoma.\(^{175}\).

Transpupillary cyclophotocoagulation:  
This procedure is limited to eyes in which a sufficient number of ciliary processes can be visualized gonioscopically, as in cases of aniridia, through a large surgical iridectomy or when broad anterior synechiae cause anterior displacement of the iris. New technology using ultra-sound cyclodestruction is currently under investigation.

Complications: \(^{169,176}\)

- Rates of complications are higher in neovascular glaucoma and with treatment protocols using more than 80 J per session.
- Persistent inflammation
- Hyphaema
- Corneal decompensation
- Vision loss
- Hypotony and phthisis

Post-operative management: [II,D]  
Consider analgesia. Topical corticosteroids and atropine instillation for 2-3 weeks. In the immediate postoperative period IOP should be monitored and the anti-glaucoma medication tapered accordingly. The effectiveness of treatment is assessed after 4 weeks.
3.6 - INCISIONAL SURGERY

3.6.1 General Principles

The different techniques of incisional surgery have different indications depending on the type of glaucoma. Their adoption depends on: [I,D]

1. the target IOP chosen for the individual situation
2. the previous history (surgery, medications, degree of visual field loss)
3. the risk profile (i.e. single eye, occupation, refractive status)
4. the preferences and experience of the surgeon
5. the patient opinion, expectation and postoperative compliance

The decision to recommend glaucoma surgery should be made in the light of published clinical trials. In the individual patient, a multitude of factors must be taken into account when deciding treatment including compliance, stage of glaucoma etc. Nevertheless, surgery should be considered whenever medical or laser treatment would appear unlikely to maintain sight in the glaucomatous eye [I,D]. It should not be left as a last resort (See Ch. 3.1). Angle-closure glaucoma is usually initially approached by laser iridotomy or peripheral iridectomy. Primary congenital glaucoma is usually treated with surgery, likely trabeculotomy or goniotomy, or combinations of filtration surgery with antifibrotic agents.

For repeated surgery, cyclodestructive procedures and tube implants are more commonly used (See FC VI).

3.6.2 Techniques

Since glaucoma surgery is successfully practiced in different ways by different ophthalmologists, a detailed description of surgical techniques is not within the scope of this text.

The primary goal of surgery is to achieve a Target IOP without additional medication. Additional medications can be used if a Target IOP is not reached by surgery alone. Success rates of a surgical method in terms of IOP lowering can be best evaluated in the absence of adjunctive medical treatment. The number of preoperative versus postoperative medications may also depend on the variable compliance of the individual patient before and after surgery. Also, it is useful to count the percentage of “successes” below a defined IOP level as in Fig. 3.3. It is also important to consider not just the IOP but complications rates and, most importantly, functional outcomes.
3.6.2.1 Penetrating Glaucoma Surgery

3.6.2.1.1 Trabeculectomy

The most widely used surgical procedure in OAG is the trabeculectomy, which produces a ‘guarded’ fistula between the anterior chamber and the subconjunctival space\textsuperscript{178,179}. The introduction of improved operating microscopes, instruments and suture materials, has led to numerous modifications and refinements of the original operation\textsuperscript{180}. Modifications include the size, shape and thickness of the scleral flap, limbal or fornix based conjunctival flaps, fixed, releasable or adjustable sutures and the use of antimetabolites and other antiscarring agents delivered in different ways to reduce wound healing\textsuperscript{81,182}. In the hands of experts the long-term success rate of filtering surgery alone, or with adjunctive medical therapy in a previously unoperated eye has been reported at up to 90%\textsuperscript{175}; there are large differences however in the criteria used for the definition of success and in the final success rates observed\textsuperscript{183-192}. The use of stainless steel implants as facilitators for performing filtration surgery should be weighted against the cost of the devices\textsuperscript{193-196}. Long-term IOP control is achieved in many cases, although some patients do require further therapy or repeat surgery\textsuperscript{178,197,198}. The alternatives to trabeculectomy in OAG include non-penetrating surgeries and drainage devices\textsuperscript{199,200-205}.

**Indications:**\textsuperscript{[I,D]}

1. In cases where other forms of therapy, like medicines or laser, have failed.
2. In cases where other forms of therapy are not suitable (e.g. where compliance or side-effects are a problem) or appropriate medical treatment is not available.
3. In cases where a Target Pressure is required to prevent clinically significant disease progression that cannot be reached with topical medications and/or laser.
4. In cases which have such advanced glaucoma and high IOP at presentation that other forms of treatment are unlikely to be successful.

Some studies have indicated that in terms of field survival, primary trabeculectomy was superior to medical treatment, but these studies may not be relevant to current medical practice as the evaluation of visual field was not done using today’s analyses, and the medical treatment options were very limited\textsuperscript{206}. More recent studies suggest that visual field progression is not significantly different whether initial treatment is medication or trabeculectomy\textsuperscript{207,208}.

The ophthalmologist must assess the risks and benefits of early surgery in each individual case.

**Long-term risks of trabeculectomy:**

Accelerated progression of senile cataracts is frequently seen after filtration surgery\textsuperscript{209,210}. Patients undergoing trabeculectomy should be advised on the symptoms of a developing blebitis/endophthalmitis including red eye, tearing, discharge or decreased vision, and should be warned to immediately seek the help of an ophthalmologist if any of these...
3.6.2.1.2 Trabeculotomy

Trabeculotomy, alone or combined with trabeculectomy, is generally used for congenital and paediatric glaucoma and is less effective in adults. It may decrease the need for further filtering and shunting procedures. A novel glaucoma procedure of trabeculotomy by internal approach was recently introduced.

3.6.2.2 Non-Penetrating Glaucoma Surgery

3.6.2.2.1 Deep Sclerectomy

In this technique, a deep lamella of corneosclera underneath the scleral flap is excised thus removing the outer wall of Schlemm’s canal. The outer layer of the inner wall of Schlemm’s canal is frequently also removed. Percolation of aqueous occurs through the porosity of the remaining trabecular meshwork, possibly through micro-perforations. When the scleral flap is repositioned, a “scleral lake” is created. A collagen implant or a hyaluronic acid device is often used to keep this scleral lake open. In a number of cases, a filtration bleb forms; long-term IOP levels appear higher than with trabeculectomy.

3.6.2.2.2 Viscocanalostomy

In this technique, hyaluronic acid is injected into Schlemm’s canal in addition to the dissection and excision of a deep lamella. The mechanism claimed to increase the outflow is the widening of Schlemm’s canal and of the collector channels as well as diffusion of aqueous from the “scleral lake”. The majority of randomised controlled trials suggests that the pressure lowering of non-penetrating glaucoma surgery is not as marked as with trabeculectomy.

3.6.2.2.3 Canaloplasty

Canaloplasty is a non-penetrating, bleb-independent, glaucoma surgery that combines a 2-flap dissection to the trabeculo-Descemet’s membrane, like in viscocanalostomy methods, with a circumferential catheterization and viscodilation of Schlemm’s canal. In addition, a 10-0 polypropylene suture is placed within the canal to tension the inner wall and the associated trabecular meshwork with the intention of preventing the Schlemm’s canal collapse thus in theory restoring natural trabeculocanalicular aqueous outflow.
This technique is indicated in POAG, pigmentary glaucoma and pseudoexfoliative glaucoma and permits combined procedures with cataract surgery [II,D]. Contraindications to canaloplasty are primary or secondary ACG, neovascular glaucoma or cases needing a low target IOP. Intraoperative or postoperative complications (hyphema, hypotony secondary to a break in the trabeculo-descemetic window, hypertension, cataract, endophthalmitis) have a lower incidence than trabeculectomy.238-242

Arguments in favour of non-penetrating glaucoma surgery:
- minimal postoperative care (no bleb management)
- reduced incidence of hypotony-related complications and cataract
- reduced incidence of intraoperative complications (iris prolapse, expulsive haemorrhage)

Arguments against non-penetrating glaucoma surgery:
- less efficient in IOP reduction (mean IOP 2-4 mmHg higher) than after trabeculectomy
- difficult technique (learning curve)
- Nd:YAG laser gonipuncture often needed for IOP control
- Anatomical unpredictability

Arguments in favour of trabeculectomy:
- lower long-term postoperative IOP
- fewer IOP-lowering medications needed postoperatively

Arguments against trabeculectomy:
- possible higher rate of cataract formation
- postoperative bleb complications
- higher risk of postoperative hypotony and related complications (choroidal detachment)
 Treatment Principles and Options

3.6.3 Methods of Preventing Filtering Bleb Scarring

3.6.3.1 Antimetabolites

Wound healing is one of the main determinants of the long-term intraocular pressure control after filtering surgery. Excessive wound healing or repair leads to scar formation in the conjunctiva. Risk factors for conjunctival scarring are young age, Afro-Caribbean/hispanic race, inflammatory eye disease (e.g., uveitis, ocular pemphigoid, Stevens-Johnson syndrome), long-term multiple topical medical therapy, aphakia by intracapsular surgery, recent intraocular surgery (<3 months), previous conjunctival incisional surgery, previous failed glaucoma filtration surgery, neovascular glaucoma. Antimetabolites such as 5-fluorouracil (5-FU) and mitomycin-C (MMC) are frequently used in patients undergoing glaucoma filtration surgery in order to reduce postoperative conjunctival scarring and improve drainage [I,A]. The use of these substances continues to be refined. Indications and techniques need to be carefully considered, particularly the use of larger antimetabolite treatment areas to minimise thin cystic blebs [I,D]. The risk of corneal epithelial erosions, epitheliopathy, late hypotony, bleb leaks, and blebitis/endophthalmitis must be considered [I,D]. The use of antimetabolites, especially MMC, is potentially hazardous, and requires careful surgical technique to prevent over drainage and hypotony, or a thin focal drainage bleb with a higher risk of infection [I,D]. New antifibrotic agents and techniques are under investigation to more specifically target and modulate the biological processes of wound healing after filtration surgery, aiming for a lower risk of complications [I,D].

3.6.3.1.1 General Precautions

The use of antimetabolites will enhance the unfavourable effect of any imprecision during surgery. It is important to assess each individual case for risk factors, and/or for the need of low target IOP and titrate the substance and dosage used accordingly based on local experience.

If aqueous flow is not well controlled persistent hypotony will occur. Strategies to increase control of flow include smaller sclerostomies, larger and/or thicker scleral flaps, tighter suturing of the scleral flap, and releasable or adjustable sutures [II,D]. Research studies suggest that a large surface area of cytotoxic treatment together with large scleral flaps and accurately sutured fornix-based conjunctival flaps lead to more diffuse, posteriorly extended non-cystic blebs giving a considerable reduction in bleb-related complications such as blebitis and endophthalmitis [I,B].

It is advisable for a surgeon not familiar with these drugs to start with weaker agents (e.g., 5-FU rather than MMC) or lower concentrations of MMC [II,D]. Antimetabolites should not enter the eye [I,D]. 5-FU has a pH of 9.0 and one drop (0.05 ml) of MMC is enough to cause irreversible endothelial damage: precautions for use and disposal of cytotoxic substances should be observed [I,D]. 5-FU and MMC are not officially approved for ocular applications. Their use in many cases as adjunctive in filtration surgery, however, has become standard clinical practice.
3.6.3.1.2 Administration

5-Fluorouracil:
  • Intraoperative use [II,D]
Concentration: 25 or 50 mg/ml undiluted solution.
Administration: intraoperatively on a filter paper or a sponge.
Time of exposure: usually 5 minutes (shorter time has minimal effect).
Rinse: with at least 20 ml of balanced salt solution.

  • Postoperative use [II,D]
Relative contraindication if epithelial problems present.
Concentration: 0.1 ml injection of 50 mg/ml undiluted solution.
Administration: adjacent to but not into bleb (pH 9), with a small calibre needle (e.g. 30 G needle on insulin syringe). Reflux from the injection site over the ocular surface should be prevented. Repeated injections are often necessary.

Mitomycin C:
  • Intraoperative use [II,D]
Concentration: 0.1-0.5 mg/ml (care must be taken in diluting it to the desired concentration).
Administration: intraoperatively on a filter paper or a sponge. Avoid contact with cut edge of conjunctival flap.
Time of exposure: 1-5 minutes.
Rinse: with at least 20 ml of balanced salt solution.

  • Postoperative use [II,D]
Concentration: 0.1 ml injection of 0.02 mg/ml solution.
Administration: adjacent to but not into bleb, with a small calibre needle (e.g. 30 G needle on insulin syringe). Reflux from the injection site over the ocular surface should be prevented. A very small amount of MMC entering the eye will irreversibly damage the endothelium. It is useful for some needling procedures but recommended only in experienced hands.

3.6.3.2 Alternative Methods of Preventing Filtering Bleb Scarring

Irradiation, PDT and inhibition of growth factors have been used, but no long-term clinical studies to support their use are yet available in[40,41].

Alternative Glaucoma Surgery

New alternative surgical techniques with the aim obtaining a higher safety profile than filtration surgery were proposed during the last several years. Under the acronym of M.I.G.S. “Minimally Invasive Glaucoma Surgery” are now collectively grouped both ab-interno and ab-externo procedures, not necessarily involving the use of an implantable device, not always bleb-independent for efficacy. The general aim would be to entail significantly less tissue manipulation than filtration surgery, with less side effects and sizeable IOP-lowering efficacy. There are no well controlled comparative
Treatment Principles and Options

trials available to support the superiority among any of these procedures nor versus trabeculectomy, for both safety and efficacy\textsuperscript{254,255}. These techniques are currently performed in selected glaucoma patients with early to moderate disease and preferably in combination with cataract surgery [II,D].

**ALTERNATIVE GLAUCOMA SURGERY (*)**

Based on subconjunctival filtration
- trans-scleral filtration, ab-interno device (AqueSys Xen)
- trans-scleral filtration, ab-externo device (InnFocus Microshunt)

Based on suprachoroidal drainage
- suprachoroidal stents, ab-interno (Glaukos iStent Supra, Transcend CyPass)

Based on Schlemm’s canal drainage/bypass/expansion
- trabecular bypass stents/canal expanders (Glaukos iStent, Ivantis Hydrus)
- ab-Interno trabeculectomy (Trabectome)
- ab-externo canalooplasty/trabeculotomy (iScience catheter)

(*) THIS LIST IS NOT ALL INCLUSIVE. The EGS does not endorse any product or procedures.

### 3.6.4 Complex Cases

Complicated glaucoma cases such as those that have failed previous surgery, secondary glaucomas, congenital glaucomas, et cetera require specialist treatment. In addition to trabeculectomy, other forms of therapy may be necessary such as drainage devices and ciliary body ablation.

### 3.6.5 Long-Tube Drainage Devices

The use of long-tube drainage devices such as those described by Molteno\textsuperscript{256-263}, Krupin\textsuperscript{264-265}, Baer veldt\textsuperscript{266-272}, Ahmed\textsuperscript{268-273,273-278} or Schocket\textsuperscript{281-284} are generally reserved for patients with risk factors for a poor result with trabeculectomy with antimetabolite [II,D], although recent trials established their efficacy and safety as a primary surgical procedure\textsuperscript{258,265} [II,B].

Factors that decrease the chances of successful trabeculectomies and, therefore, make tube surgery attractive, include previous failed filtering surgery with antimetabolites, excessive conjunctival scarring due to previous ocular surgery with severe conjunctival or surface disease, active neovascular disease, paediatric aphakia, or where filtration surgery is going to be technically difficult\textsuperscript{286,287} [II,D].
3.7 - CATARACT AND GLAUCOMA SURGERY

When glaucoma surgery is indicated and there is a visually significant cataract the two procedures can be performed combined or sequentially. The decision is to be made according to the clinical findings, after discussing with the patients advantages and disadvantages of each approach [1,6].

In case of angle closure or narrow angle approach, it is important to evaluate the lens as a component of the raised IOP [1,6] (See also Ch 2.4).

Small-incision phacoemulsification cataract extraction is one of the most relevant surgical advances for our glaucoma patients. It allows faster and better visual recovery, and with appropriate techniques it is safely applicable in cases with small pupil, shallow AC or pre-existing filtering blebs. Furthermore it can be combined effectively and safely with filtering procedures, including trabeculectomy, miniature drainage implants and deep sclerectomy [205,288-290].

Different new glaucoma surgical techniques which can be combined with phacoemulsification (i.e endoscopic cyclophotocoagulation, trabecular bypass stents, ab interno trabeculectomy and canaloplasty) have been proposed in the last years [291]. Randomized clinical trials are presently needed to clarify this topic.

Despite the improved results of small incision phacoemulsification and of filtration surgery with anti-metabolites there is no evidence to support a generalized switch from sequential to combined surgery and vice versa [1,6].

In summary:

- Modern phacoemulsification with clear cornea incisions does not interfere with subsequent glaucoma surgical procedures [292]
- The development or worsening of a visually significant cataract is common after glaucoma surgery [209]
- Cataract surgery performed after trabeculectomy can affect the IOP control [200,203]
- Cataract surgery alone may be of limited benefit in lowering the IOP in open angle glaucoma and the effect appears to be proportional to the preoperative IOP values; such effect may be greater in angle closure glaucoma / narrow angles and appears to be proportional to the degree of anterior chamber opening [294-296]
- Combined procedures allow for greater IOP reduction and fewer IOP spikes in the immediate postoperative period than phacoemulsification alone [297-299]
- The success rate of combined phacoemulsification and filtration surgery is usually not as favourable as filtration surgery alone and the use of antimetabolites is recommended in all cases.
