Conjunctival biopsy in adult form galactosialidosis

Tomoaki Usui, Shoichi Sawaguchi, Haruki Abe, Kazuo Iwata, Kiyomitsu Oyanagi

Abstract
Conjunctival biopsy was performed in two siblings with adult-form galactosialidosis. Electron microscopically, several types of intracytoplasmic inclusion were observed in the fibroblasts in conjunctival stroma, lymphatic capillary endothelial cells, Schwann cells, and epithelial cells. Membrane-bound vesicles with fibrillogranular content were frequently observed, and occasional lamellar structures were noted in these inclusions. Dense granular inclusions and oil droplets were also seen. Dense granular inclusions have not been reported in this disease previously.

(Br J Ophthalmol 1993; 77: 165–167)

Galactosialidosis is a lysosomal storage disease characterised by decreased β-galactosidase and sialidase activity. Clinical features include myoclonus, cerebellar ataxia, epilepsy, mental retardation, angioedema, gargoyle-like facial features, skeletal dysplasia, and visual disturbance.1–3 The cause of this disease is thought to be a defect of a 'protective' protein which is necessary for activating both β-galactosidase and sialidase.4–6 This disease is classified into three types according to age of onset: (1) the early infantile form, (2) the late infantile form, and (3) the juvenile/adult form.7 Several reports on conjunctiva in this disease have described variable findings which showed cytoplasmic vacuoles in the fibroblasts, epithelial cells, endothelial and goblet cells,8,9 and lamellar structures in the Schwann cells10,11 but no other abnormalities.12 Agreement on these conjunctival findings has not been reached because of the rarity of this disease. We studied the conjunctiva of two siblings with adult-form galactosialidosis and found a new inclusion body in the conjunctival cells.

Patients and methods
The patients were a 41-year-old man and a 46-year-old woman. Their detailed clinical ophthalmic findings have been described in a previous report (cases 1 and 2).13 The onset of disease was when they were teenagers. Their conjunctivas showed mild venous congestion, microaneurysms, and venous dilatation, although these changes might be seen in aging, arteriosclerosis, and vascular hypertension.

Informed consent was obtained from these patients. Biopsies were performed by applying topical oxybuprocaine hydrochloride drops. A piece of bulbar conjunctiva (approximately 1 × 1 mm) was elevated with forceps and excised. Antibiotic ophthalmic ointment was instilled, and the patients were allowed to leave the clinic. No complication or morbidity occurred.

The specimens were fixed in 3% glutaraldehyde and 1% paraformaldehyde in a 0.1 mol/l phosphate buffer (pH 7.3), post-fixed in 1% osmium tetroxide, dehydrated through a graded ethanol series, and embedded in epoxy resin (Epon 812). Sections of 1 μm thickness were stained with toluidine blue. Ultrathin sections stained with uranyl acetate-lead citrate were examined under the electron microscope (H-7000, Hitachi Instrument Service Co Ltd, Tokyo, Japan).

Figure 1 The fibroblast in conjunctival stroma (case 1). Abundant vesicles with some fibrillogranular content were noted.

Figure 2 Schwann cell (case 1). Plenty of membrane-bound vesicles were observed. Dense granular materials were also seen in some vesicles (white asterisks). BM = basement membrane.
Results
The fibroblasts in conjunctival stroma were filled with abundant vesicles having a fibrillogranular content (Fig 1). Schwann cells also had many membrane-bound vesicles (Fig 2). Dense granular materials were also seen in some vesicles. The conjunctival epithelium had many large membrane-bound vesicles with abundant fibrillogranular content but little lamellar structure (Fig 3). Some fibrillogranular content, dense granular inclusions, and vesicles were seen in the cytoplasm of the conjunctival fibroblast (Fig 4). The stromal fibroblasts appeared filled with vesicles (Fig 5). A few vesicles were filled with dense granular inclusions having lamellar structures. Fibrillogranular structures containing a small number of oil droplets were occasionally seen. Laminated lamellar structures combined with fibrillogranular structures were also seen in the fibroblasts (Fig 6). The lymphatic capillary endothelial cells contained few membrane-bound vesicles. Membrane-bound vesicles in endothelial cells appeared less predominant compared with those seen in the fibroblasts and conjunctival epithelia. Similar findings occurred in both patients.

Discussion
There have been a few reports of conjunctival findings of patients with confirmed deficiencies of both neuraminidase (sialidase) and β-galactosidase activities. Patients with the adult form have cytoplasmic vacuoles in the fibroblasts, epithelial cells, endothelial and goblet cells, and lamellar structures in the Schwann cells. In a case of the late infantile form, Goldberg et al reported that no abnormalities in the conjunctival cells were found although a conjunctival biopsy specimen from a subject who was deficient in β-galactosidase had values 55% of those of controls.

Our results showed several types of inclusions, including membrane-bound vesicles having a fibrillogranular content, dense granular inclusions, lamellar structure, and oil droplets. Membrane-bound vesicles were frequently observed, however, the other forms were rare. Lamellar structures were occasionally seen within the membrane-bound vesicles. Intracytoplasmic inclusions in the conjunctiva were quite different from those observed in the retina, which had an almost concentric or wavy form, with parallel lamellar inclusions and membrane-
bound, partially crossing, and parallel lamellar inclusions. The membrane-bound vacuole with fibrillogranular content observed in our cases resembled the intraneuronal inclusion seen in the central nervous system (cerebral cortex, brain stem, basal nucleus of Meynert, etc.)

The cytoplasmic vacuole and lamellar inclusion seemed to correspond to mucopolysaccharides and lipids, respectively.

Dense granular inclusions have not been reported in this disease before. These storage materials have not been precisely determined in conjunctiva. Further investigation is needed to determine the metabolic mechanisms in the conjunctiva.
