Intraocular lens implants and risk of endophthalmitis

EDITOR,—We would like to comment on the paper by Bainbridge et al.

The aim of their study was to investigate the possible association between the use of three piece foldable silicone polymethylacrylate intraocular lenses and increased risk of endophthalmitis, and indeed the investigators have met this goal and proved this association in an elegant study.

In addition, the authors have supplied the reader in their article with very important information (Table 1) that was not discussed. All of the seven cases had a medical history of one or more systematic diseases that may affect the immunological conditions of the patients and contribute to the development of postoperative endophthalmitis. In fact, one patient with plastic anaemia was excluded from the statistical analysis.

Comparing the patients with endophthalmitis with control subjects in a random fashion, even in small series, may reveal additional risk factors such as medical history. The addition of a controlled group of patients undergoing the same surgery who did not develop endophthalmitis could add a lot to the strength of the study.

We believe that endophthalmitis develops when several risk factors are present. We are obliged to take all these factors into consideration before, during, and after surgical procedure, especially in debilitated and immunosuppressed patients. In this kind of patient prophylactic considerations must be borne in mind, including adequate preparation of the patient and surgical field, antibiotics, experiences surgeon, safer instruments, and IOLs.

Pupillary abnormality

EDITOR,—In a recent issue of the BJO, we had the opportunity to read the interesting case report on pupillary abnormality, by Malla.1 The author reported a gross persistent pupillary membrane (PPM) in both eyes of a 33 year old male child. The brownish membranes were detected by a school teacher. The child confirmed the presence of poor vision in bright sunlight after a precise questionnaire concerning this symptom. The visual acuity in our case under ordinary room illumination was 20/40 in both eyes. Nevertheless, when measured while the light of the indirect ophthalmoscope was shone into his eyes at an angle of 45°, visual acuity was surprisingly reduced to 20/100 in both eyes. Similarly, Kumar et al.2 also reported two cases (aged 15 and 17 years) of hyperplastic pupillary membrane presenting with marked decrease of visual acuity in bright sunlight. In the latter case, these authors recorded a reduction in visual acuity from 20/40 to 20/200 after instillation of pilocarpine eye drops or projecting the indirect ophthalmoscope light at a 30° angle.

It is widely accepted that asymptomatic cases of PPM usually don’t require excision beyond the sensitive period of amblyopia.3 Nevertheless, some cases presenting with significant visual loss in bright sunlight required surgical or Nd:YAG laser intervention. Besides visual acuity concerns, cosmetic ocular disfigurement caused by PPM may also be considered as a reason for intervention in some patients.

Reply

EDITOR,—I have just reviewed the patient with the bilateral persistent pupillary membrane. Visual acuity both for distance and near remained unchanged (6/6 partially and N5 in each eye) with pupils constricted by showing the light of an indirect ophthalmoscope at an angle of 45°. The patient has no visual complaints and is unaware of any decrease in vision in bright light.

“Cycloidiode”

EDITOR,—I read with considerable interest the paper by Spencer and Vernon4 on the results of a standard protocol for trans scleral diode laser cyclophotocoagulation (“cycloidiode”). The particular importance of their study regard to more widespread use of this therapy lies in the high percentage (64%) of treated eyes with pretreatment Snellen acuity, and while a third of these eyes lost 2 or more lines of Snellen acuity, it appears that in some cases, not directly attributable to the cycloidiode treatment, with particular note being made of the low rate of ciliary macula oedema.5

The authors report success rates in achieving IOP control with a standard protocol, but, as in most other published series, record findings after “repeat as necessary” retreatments (in this study up to five in number). While this is of obvious interest to clinicians, it may be of almost equal utility to know the effect of a single treatment. In an earlier paper, also using a standardised treatment protocol for cycloidiode treatment,6 an attempt was made to elucidate any dose-effect relation from single cycloidiode treatment session. With a single treatment totalling 90 J through 360°, a mean lowering of IOP of 48% was achieved, but the predictability of outcomes in this series was hampered by the high number of neovascular glaucoma (NVG) cases, which are recognised as having highly variable responses.7 It would seem that Spencer and Vernon are uniquely placed—with their standard protocol and low numbers of NVG cases—to provide data pertaining to any dose-effect relation from a single treatment, information which may be used to enhance the predictability of the procedure for individual patients.

The authors also note that their cohort was largely free of cases having had previous cyclodestractive procedures: that is by definition not true, however, of all the retreatment cases, and the authors appear not only to have been reasonably forthright in their pursuit of an IOP <22 mm Hg, but also to have applied the same laser dose irrespective of the number of retreatments, with their retreatment plan leaving no untreated quadrant. In the series noted above, using a half standardised single treatment (45 J over 180°) for cases judged clinically to be at risk of hypotony (which included cases having had previous cyclodestractive procedures) a mean IOP reduction of 36% was still achieved.8 It would therefore be of great interest to know whether any cases in Spencer and Vernon’s paper were excluded from retreatment, despite inadequate postoperative IOP control, because of a concern about possible hypotony; similarly, it would be useful to know whether “all comers” were treated in the study—to have whether there were specific exclusions from standardised cycloidiode treatment because of this perceived risk.

Reply

EDITOR,—We thank Dr Walland for his interest in our paper1 and for summarising the results of his study2 which was published following our paper’s submission. It is difficult to quantify the dose-effect from a single treatment in cyclodiode because (a) it would depend on the follow up period as the effect may diminish with time, and (b) one would have to continue all the prelaser antiglaucoma medications (not always desirable) to see the true effect.

However, we can analyse the “single dose effect allowing for a reduction of medications” from our study by examining the results of only those eyes which had one treatment session (32). This subgroup contained seven primary open angle glaucoma, five aphakic, two pseudophakic, seven uveitic, three corneal/PK, four rubecic, one silicone oil, and three trauma cases, thus representing the whole spectrum of the cohort treated. Although this subgroup, by definition, selects out the “best case scenario”, this was achieved in over 50% of cases treated. With a mean follow up of 19 months, the IOP of this subgroup decreased from a mean of 31.2 mm Hg to a mean of 16.2 mm Hg, with a 45% mean percentage reduction. This was associated with a reduction in numbers of patients taking acetazolamide from 88% to 6% and a mean medication usage from 2.2 to 1.2. None of these results differs significantly from those of the whole cohort.

In our study no eyes were denied treatment or treatment because of a perceived risk of hypotony, and “all comers” were indeed treated by this modality if enhanced filtering surgery was considered contraindicated. It may be of interest to know that 71% of the cases were referred into our service from non consultants throughout our region (population approximately six million). We cannot state that all eligible cases were treated by us, but we believe our cohort is likely to be representative of cases referred to other glaucoma specialists with a similar population to that found in the East Midlands of England.

We note that, in Walland’s study, the mean prelaser IOP at a mean of 10.4 months was 25.8 mm Hg with only 55% <22 mm Hg even when a “full” treatment of 90 J was delivered. Although this may be as a result of the large numbers of patients with neovascular glaucoma in this group, it may also be due to the time and power output settings used (1.5 seconds and 1.5 W). With our settings of 2 seconds and 2 J per shot we were able to control IOP with a 65.7% reduction using a mean of 1.7 treatments in our neovascular subgroup. Reducing the output per shot, as in Walland’s study, may result in a reduction in treatment effect overall despite higher total energy delivered. This could be due to the transmission attenuation in certain eyes, operator technique variation, probe output differences, and ciliary process uptake/susceptibility factors.

Is non-arteritic anterior ischemic optic neuropathy related to homocysteine?

EDITOR,—We read with interest the paper recently published by Kawasaki et al.3 They suggested that hyperhomocysteinaemia may have a role in the occurrence of non-arteritic anterior ischemic optic neuropathy (NAION) in non-diabetic patients younger than 50 years, and raised the question of the frequency of the methylene tetrahydrofolate reduc- tase (MTHFR) C677T mutation in this population.

There have been anecdotal reports of thrombotic tendencies in patients with NAION.4 Although NAION is most probably related to compromised posterior ciliary artery circulation at the optic nerve head (so called “disc at risk”), it is also possible that some systemic factors such as hyperhomocysteinaemia and the MTHFR C677T mutation may enhance local athero- genesis at the level of the posterior ciliary arteries, thereby precipitating the develop- ment of NAION in those at risk for the disease.5 Kawasaki et al could not demon- strate any change in plasma homocysteine and homocysteine and NAION. However, the blood sample used to measure the homocysteine was obtained after the clinical event. Since homocysteinaemia fluctuates, it is possible that the general population have underesti- mated the frequency of hyperhomocysteinaemia. We recently investigated prospectively the presence of hyperhomocysteinaemia and the MTHFR C677T mutation in patients with acute NAION.

Blood samples from 14 newly diagnosed patients with acute NAION presenting to our centre over a 1 year period (May 1998 to May 1999) were evaluated for serum creatinine, serum and red blood cell folate, B12, and total plasma homocysteine levels, as well as the C677T polymorphism in the MTHFR gene. There were 10 men and four women (13 white and one Asian), ranging in age from 28 to 68 years (mean aged 42.8 years). All patients had a disc at risk in the fellow eye. Five patients subsequently suffered NAION in their second eye. Four patients (28.5%) were heterozygous and one was homozygous for the C677T mutation in the MTHFR gene, which does not differ from the frequency reported in the general population.6 Only one of these five mutation positive patients had bilateral NAION. The homocysteine level was within normal range in all 14 patients, as were the creatinine, folate, and B12 levels. Homocysteine levels were not higher in the mutation positive patients than in the mutation negative patients. Mutation positive and mutation negative patients did not differ with respect to clinical data concerning risk factors for NAION or coexisting vascular disease.

Although this is a small study, these results suggest that homocysteine and the C677T MTHFR polymorphism do not have a role in the occurrence of NAION. Our results are similar to those of Kawasaki et al and the frequency of the MTHFR mutation is not higher than in the general population. As recently re-emphasised,7,8 laboratory testing for hyper- coagulable states in a patient with NAION without past medical history or family history of a thrombotic event would be unwarranted. However, it is still possible that for a given individual already at risk for AION, a thrombogenic predilection may be a trigger for an acute ischaemic event of the optic nerve head. If there are clinical findings suggestive of a thrombogenic tendency, such as recurrent thrombotic events or a family history of thrombosis, or if there is no disc at risk in the fellow eye in a younger patient without vascular risk factors, an investigation for hereditary and acquired thrombophilic markers may be justifiable.

This study was supported in part by a departmental grant (department of ophthalmology) from Research to Prevent Blindness, Inc, New York, New York, by core grant P30-EY06360 (department of ophthalmology) from the National Institute of Health, Bethesda, Maryland. EDITOR,—We thank Biousse and colleagues for their comments on our article and their corroborative study. We agree that an exten- sive hypercoagulable evaluation is not war- ranted in patients with NAION who have typical risk factors, including older age. The yield from such an evaluation in young patients with NAION, especially those with- out known risk factors or those who suffer recurrent events, still needs further elucidation.

Laser pointers: not to be taken lightly

EDITOR.—We recently treated a 16 year old boy whose friends exposed both his eyes to a laser beam alternately for 20 seconds from a distance of around 1 metre in the course of horseplay with a key chain laser pointer (class 3a diode, 670 nm, maximum output 5 mW). Immediately thereafter, his vision was blurred bilaterally and he noted a red central scotoma in each eye. These symptoms resolved sponta- neously within 2 days. An eye examination performed 3 days later disclosed that his vision and visual fields were normal, but there were retinal pigment epithelial disturbances which appeared in fluorescein angiography as...
a window defect type hyperfluorescence in both eyes close to the fovea. The macular burns persisted throughout an 8 month follow up period. The literature describes two cases of unilateral macular damage from laser pointers (class 2 diode, 670 nm, maximum output 1 mW and class 3a diode and 670 nm, maximum output 5 mW), 1, 2 and two other cases of bilateral decreased vision due to large retinal photocogulation scars from class 3a laser pointers. 3

In his review of the safety of laser pointers, Marshall 4 comprehensively described the classification of the lasers according to hazard. However, no small part of the message of his piece is that in a letter to the Lancet, he unmistakably designed to placate the reader into believing that laser pointers are harmless. After witnessing the persistent injury to our own patient and reading the reports of four others who were likewise hurt by this device, we are appalled. The laser pointer is not an innocent toy. It damages the eye and should not be made freely available to youngsters whatever its strength, while the label of the laser pointer only "cautions" users not to shine the laser pointer light into an eye.

Media “hype” underpinning reports in the popular press and the pernicious avarice of individuals lurking in wait for opportunities to claim compensation for spurious injury seem to have galvanised estimable individuals to rush to the defence of this instrument. We contend that laser pointers which are regarded as being “safe” carry the risk of potential damage to the eyes and that more such cases will be detected once physicians are alerted to this possibility. We believe that the public must be instructed in the safety measures that need to be taken when using the laser pointer and that they be made aware of the potential hazards associated with improper use. We recommend that use of laser pointers in public should be controlled and the close devices be kept away from children.

BOOK REVIEWS

The fourth edition of this standard text lives up to its enormous reputation. Jack Kanski sets out “to provide the trainee with a systematic and easily assimilated introduction to ophthalmology and a reference and update for the more experienced practitioner”. Undoubtedly these clear and circumscribed aims are well met in this beautifully and even more lavishly illustrated text. In addition to covering all those aspects of ophthalmology, including retinopathy, a new chapter on ocular trauma has been added in addition to descriptions of new surgical techniques and some pruning of outdated material.

This is and has been an extremely successful primer text for the trainee ophthalmologists and one might ask why this book rather than the many other texts available. Perhaps the answer lies in part in the approach taken with this text which is distinctly "patient oriented": one can almost envisage the author examining the patient presenting to the ophthalmic clinic by staring systematically at the front of the eye and working his way posteriorly. Overall this is an excellent starting text. The section on neuro-ophthalmology contains several excellent illustrative radiological scans. Overall this is an excellent starting text. If there is any criticism that can be levelled at this classic text, it is that it leaves this reader thirsting for further information.

This is an important and thought provoking book which is not only not within the medical profession but also by interested parties such as health economists and government officials whose responsibility it is to set budgets for healthcare programmes, I think it will also be of great interest to the lay public. The practice of medicine is as susceptible to the whims of fashion and pervasive ideology as any other human activity. It is therefore interesting to investigate how these fashions are set. J Le Fanu has a background in medical and scientific journalism, having spent time on the staff of the Daily Telegraph, one of the UK’s broadsheet newspapers. His thesis is that despite the significant advances in treating disease which reached their peak in the post-war years, the promise of modern medicine as we are at the end of the century has failed to materialise. In fact, Le Fanu contends that much of the advances in the first half of the 20th century were accidental or at best serendipitous, citing as examples the discovery of antibiotics, which was never predicted, or the use of chloroquine for rheumatoid arthritis, which was found from the clinical observations of patients treated for malaria. Even the success of aggressive chemotherapy for childhood cancer was the result of a determined but empirical approach of testing systematically multiple drugs in combination. The same approach has now been shown to be successful in the treatment of AIDS which one could or should think of as a much more daunting, even more lethal disease. This “success” is not based on scientific knowledge, despite the vast amount that has been discovered about the AIDS virus, but simply on a “suck it and see” approach.

In contrast, the great promise of the new genetics or of the social theory of disease has not held up according to the author. The amazing strides in our knowledge derived from molecular biology led to the rapid acceptance of the possibilities of gene therapy but these have emphatically failed to deliver, despite the intellectual satisfaction that these smart ideas generate. Similarly, in the wake of studies showing a clear epidemiological correlation between smoking and lung cancer the social theory has sought to link almost every disease for which there is not an obvious infectious cause to some lifestyle or nutritional source mostly blamed on Western society. Le Fanu firmly believes that the errors at the feet of a few individuals who inveigled themselves into influential positions—for instance, in the American Medical Association, and with the support of the major drug companies have utterly and unfortunately changed our lifestyles to the point where the vast majority of healthy individuals are worried more about their health than ever before while being encouraged to ingest drugs such as cholesterol lowering drugs. There is little evidence that they will actually do for the individual what the statistics tell us: let alone prevent the individual patient from dying of a heart attack. Le Fanu suggests that it would be possible to rectify this situation overnight by closing down all university departments of epidemiology. Ophthalmology has not been immune to these problems (see the revised recommendations concerning laser treatment for diabetic patients with clinically significant macular oedema and the 20/20 vision, Arch Ophthalmol 1999; 117:675).

This book is not a sustained attack on modern medical practices nor is it written purely to debunk all of medicine’s current theories and who then promulgate smart ideas generate. Similarly, in the wake of the major drug companies have utterly and unceremoniously changed our lives by translating these into new cures for disease. The book does contain implicit and sometimes explicit criticism of medical scientists who effectively produce ever more current theories and who then promulgate these in a way that alters people’s lifestyles. In particular, the book has much to say about the dangerous part played by the major pharmaceutical companies in medicine. Many who read this book will be able to relax about their imputed health problems, to feel confident about their ability to ward off many of the supposed hidden dangers which face them out there, and to take much of what they hear from the medical pundits with a pinch of salt. The author offers hope for the future and, in particular, calls for a return of the experienced physician who exercises good clinical judgment, with a dash of common sense.
