Advancing microsurgical instrumentation into the 21st century

EDITOR,—It seems a surprising omission from the Waldoes’ recent commentary on the future of microsurgical instrumentation not to have mentioned contamination with specific reference to transmissible spongiform encephalopathies (TSE).

We agree that prion protein is not reliably destroyed by most disinfection or sterilisation procedures, including autoclaving at a temperature as high as 138°C for an hour. Although more effective methods, such as exposure to combinations of alkali and heat, are being developed they may require instruments to be particularly durable. Also fine, and particularly, toothed instruments require thorough cleaning before sterilisation by current procedures, to avoid retention of tissue.

Although there is no clear evidence of the transmission of TSE from one patient to another by ophthalmic surgery other than through corneal transplantation, the only extant Department of Health guidelines state that any instruments used on patients with Creutzfeldt-Jakob (CJD) or suspected of this condition must be destroyed. Patients with classic sporadic CJD are predominantly in their 60s and may come into contact with ophthalmologists because of cataract, glaucoma, and macular degeneration or because of visual symptoms caused by their condition.

The number of individuals in the UK who are incubating variant CJD (vCJD), believed to be the human form of bovine spongiform encephalopathy (BSE), is unknown. Prion protein has been shown to be present in the tonsils and appendices of its victims; the possibility of it being present in the eye, and particularly in the retina and optic nerve of apparently healthy individuals, must unfortunately be entertained. The Department of Health has identified neurosurgery and ophthalmology as areas of particular risk, though arguably many forms of routine surgery could in theory pass on prions from one patient to another via contamination of instruments.

The only certain way to avoid the as yet unquantifiable risks of ophthalmic (or any set) surgical instruments as vectors of transmissible disease is for them to be disposable. Even then, the temptation to reuse disposable instruments for cost containment will be present. The Medical Devices Agency has already issued guidelines on devices that touch the eye, in particular contact lenses, though the full implementation of these recommendations is not possible without the eye services grinding to a halt. Nevertheless, those situations when disposable instrumentation could be implemented—for example, eye banking, without compromising standards or indeed increasing costs, by saving on tracing and autoclaving.

We agree that surgeons, engineers, and manufacturers should engage in an active and productive debate on instrumentation for the 21st century, but this should include further initiatives to utilise new materials to facilitate disposable instruments. This dialogue may also bring about a rethink of the number of instruments on trays, the majority of which may be autoclaved time and again without being used.

Reply

EDITOR,—I thank Tullo and Taylor for their interest in our commentary and for highlighting a very important issue regarding the future of microsurgical instrumentation. Instrument manufacturers are aware of the implications of contamination, in particular from transmissible spongiform encephalopathies. We agree that there is a need for everyone associated with “high risk of transmission” surgery, such as ophthalmology, to rethink the strategies towards avoiding the risks of contamination. This needs to include a review of cleaning and sterilisation procedures as well as surgical instrument design.

As far as engineers and manufacturers of ophthalmic surgical instruments are concerned, there needs to be a complete reconsideration of instrument design. This includes a review of the materials being utilised, taking into account the need for durability to rigorous sterilisation procedures as well as cost. The assembly of the instruments must enable easy and thorough cleaning, while an evaluation of the methods by which manufacturing costs can be kept to a minimum may enable the production of affordable disposable instruments. Despite such criteria, it is important to maintain the high standards of quality which are required from instruments used in this field of surgery. This poses an interesting challenge and one which we agree requires an active and productive discussion from surgeons, eye bank technicians, engineers, and manufacturers.

Central serous chorioretinopathy complicated by massive bilateral subretinal haemorrhage

EDITOR,—We read with interest the report by Lip et al., describing a 43 year old Asian man with central serous chorioretinopathy (CSCR) complicated by massive bilateral subretinal haemorrhage. The authors attributed the massive haemorrhage to CSCR itself. As the authors have pointed out, massive subretinal macular haemorrhage could be due to several causes, including idiopathic polypoidal choroidal vasculopathy (IPCV). In their article, there is a colour fundus photograph of the left eye (Fig 3A) showing a small red nodule in the centre of fovea with surrounding subretinal haemorrhage. The lesion corresponds to the hyperfluorescent spot in the fluorescein angiogram (FA) and indocyanine green angiogram (ICGA) in the same figure (Fig 3B, C). These clinical pictures are still compatible with the diagnosis of IPCV, although the presence of hyperfluorescent IPCV precludes the visualisation of other classic features of IPCV. Recently, we have had the opportunity of examining a similar patient presented with massive subretinal haemorrhage in one eye, with a history of CSCR documented by FA. ICG of the other eye showed the presence of classic signs of IPCV including dilated choroidal vessels with terminal polyps. As CSCR and IPCV are both choroidal vascular diseases, their presence in the same eye or same patient is possible.

is certainly possible. In this case, however, we feel there is no evidence that our patient had IPCV.

Retinopathy and myopia of prematurity

EDITORS—We have some comments on the recently published article by Choi et al. dealing with long term refractive outcome and ocularometry variables in Korean children of very preterm delivery. As for the sample under study (n=65) there are certain points to state. A main point is that 17 eyes (out of the 125 under study) survived their ROP and the subsequent cryotherapy. The eventual full sample myopia frequency of 67% is very high. No account is given of visual acuity or blindness data. A main point is that 17 eyes developed macular dragging after the cryotherapy (and apparently there were no cases of more advanced retinal detachment). The remaining 50 eyes with cryotherapy were even reported as having no cataract. ROP was follow up at the ages of 3 months, 3 years, and 6 years. With the overall ROP severity recorded, it is impossible to judge whether 27% of the ROP cases had cicatricial sequence of the retina, the narrow definition apparently being dragging of the macula.

In this context one may wonder why the authors preferred Reese’s classification of the early 1950s, and not its acknowledged successor regarding cicatricial ROP. It even appears as if the Reese classification was not quite followed to the letter.

For comparison, in the same issue of BJO in the US university clinic material published by Saunders et al.,1 143 preterm subjects were collected over 13 months and 12% acquired threshold or prethreshold ROP. To our knowledge there is no reason to assume that the Korean university clinics are not on quite such a developed level, nor that the infant susceptibility regarding ROP should markedly differ from what is known from nearby Asian metropolises. The authors further state that there are no previous longitudinal reports in the field. Depending on how “longitudinal” is defined, however, there are several studies of a rather similar sample used, and with emphasis on subsequent refraction and ocularometry keratometry results.14 It is from these studies that our present knowledge is compiled.

This knowledge may be summarised as follows: In ordinary myopia the correlations between the “minor” refractive factors (corneal power, anterior chamber depth, lens thickness) all tend to reduce the myopia otherwise indicated by the published main factor—the axial length elongation. Contrarily, as regards myopia of prematurity: the corneal curvature is steeper, anterior chambers are more shallow, and lenses thicker; axial lengths therefore appear relatively short for their myopia.14 Myopia is still mainly axial, but not so axial as usual. Though emphasising anterior segment features in high myopia the authors ignore or discard their own higher corneal powers compared with presumed norm values. Apparently the generally steeper corneas may have contributed 1–1.5 D to the myopia.

Finally, it was interesting to see the split up according to cryotherapy for the 29 eyes with cicatricial sequence of the ROP cases. Their 6 year myopia averaged −2.97 D. In contrast, those without cryotherapy had −6.18 D. This might be interpreted as some protection exerted by the cryotherapy against the relative developmental involution that myopia of prematurity seems to represent. Otherwise, the cryotherapy itself has been blamed for generating myopia,16 but here it seemed to be subordinate to the severity of the eye disease for which the ablation therapy was applied.

7 Fledelius HC. Myopia of prematurity, clinical signs indicated that limbal stem cell transplantation in patients taking postoperative steroid treatment, particularly in whom HSV keratitis is the primary corneal diagnosis. This possibility would be less likely if the indication for transplantation was a corneal disorder other than HSV or viral infection was excluded by pathological study of the corneal specimens. It is also possible that in these specimens the immature inflammatory findings represent HSV recurrence accompanied by allograft rejection. However, we question the validity of the conclusions relating to rejection in specimens from those patients with signs indicating possible viral keratitis. This may explain in part, for example, the counterintuitive finding that the number of CD1a/MHC class II double positive cells was not significantly higher in a group with severe inflammation at the time surgery than in the group with no inflammation.

EDITORS.—Larkin’s letter questions the primary diagnosis in the patients listed in Tables 2 and 3 and suggests possible herpes virus origin of the disease. The question arises from our description of postoperative complications in some of our patients which include graft melting and perforation. We agree that graft melting is not a typical feature of corneal graft rejection.

We would wish to clarify the clinical status of our patients. Only in two patients was the primary condition related to HSV infection. In all other grafts, in which the patients had surface wound healing problems, the diagnoses included lime burns, keratoconjunctivitis sicca, and Stevens–Johnson syndrome without signs of herpes simplex virus keratitis. In these patients graft epithelial healing problems are related rather to the limbal stem cells and tear film deficiency than to infectious causes. In fact, it is recognised that there are sometimes difficulties in distinguishing graft rejection from inflammation due to chronic antigenic defect. In our patients we made a diagnosis of rejection in association with epithelial healing problems. We cannot exclude the possibility of HSV infection of the transplanted grafts but clinical signs indicated that limbal stem cell
deficiency was the cause of the epithelial healing problem and subsequent graft melting.

MARTIN FILIPEC

Late onset lattice dystrophy

EDITOR,—I read with great interest the article by Stewart et al. on late onset corneal dystrophy with systemic amyloidosis (familial amyloidosis of the Finnish type/Merotoja syndrome) and their claim that this was the first case described in the UK. I would like to point out our case report published in the BJO in November 1999. We described a classic case of Merototoja syndrome in an English woman which was confirmed by genetic testing of the patient and her daughter who both demonstrated the point mutation on the gelsolin locus on chromosome 9.

The authors bring to our attention a second family with this disorder and rightly state that the concept of a geographically limited disorder—namely, familial amyloidosis of the Finnish type, must be treated with caution as interest in this condition can occur elsewhere in the world.

In our patient, immunocytocchemistry of the corneal button removed at keratoplasty showed no labelling of the amyloid deposits with antibodies to pre-albumin, amyloid A, and gelsolin. This was in contrast with other studies where amyloid stained with antisera to amyloid P. This was in contrast with other studies where amyloid stained with antisera to amyloid P. This was in contrast with other studies where amyloid stained with antisera to amyloid P.

In our patient, immunocytocchemistry of the corneal button removed at keratoplasty showed no labelling of the amyloid deposits with antibodies to pre-albumin, amyloid A, and gelsolin. This was in contrast with other studies where amyloid stained with antisera to amyloid P. Whether this represents a subtype of the condition is uncertain and it would be interesting to compare findings with Stewart et al. although there is no mention of immunocytocchemistry results in their paper.

BOOK REVIEWS

The Art of LASIK is the second edition of the well known Eximer Refractive Surgery: Practice and Principles, by Jeffrey Machat, Stephen Slade, and Louis Probst. It is an outstanding reference, not only for the refractive surgeon but also for anyone managing or co-managing patients who have had or plan to have laser refractive surgery. With the successes of refractive surgery—the myopes, hyperopes, and astigmats being on everyone's lips, it would be easy to become complacent as the number of successful cases and satisfied patients continues to mount. While the first edition placed great emphasis on procedures and techniques, there have been numerous advances in both instrumentation and in refinements of surgical technique in the intervening years to warrant a second edition. However, as one reads this volume, which has the contributors and clinical expertise of 45 clinicians worldwide, one cannot help but be impressed with its comprehensive scope, but more importantly, with the authors' concerns for avoidance of preventable conditions and their detailed management plans when postoperative complications do occur. The Art of LASIK also provides the reader with innovative chapters on the use of LASIK in patients with previous ocular surgery, as well as topography assisted laser ablation, and management of complex LASIK cases.

As one would expect, section one's introductory chapter deals with refractive surgery options and with the historical evolution of today's LASIK procedures from keratomileusis, PRK, keratophakia, epikeratophakia, and automated lamellar keratoplasty, as well as newer peripheral mass addition techniques (such as intracorneal rings and gel injection adjustable keratoplasty). Dr Machat presents an excellent chapter on the fundamental principles of excimer lasers and excimer laser surgical ablation, including discussion of the need for continual maintenance and the continual calibration of such lasers. He right-fully points out that despite the phenomenal precision of tissue ablation with the excimer laser, PRK's limitations revolve around the much less predictable effects of wound healing, thus paving the way for LASIK's embrace by refractive surgeons worldwide. A useful section dealing with Munnerlyn's formula for ablation depth and mathematical considerations involved in microkeratome produced flap thickness, maintenance of adequate residual stromal thickness, and diameter of ablation zone is provided, along with specific highlighted “pearls” showing the maximal correction possible using various LASIK techniques. These highlighted clinical pearls are present throughout the book, which serve to nicely emphasise major points and clinical observations.

LASIK surgeons will find the chapter on predictive formulas for LASIK most valuable, with nomograms provided for various levels of refractive correction for the different lasers. The discussion of adjustment factors, based on altitude of the treatment centre, age of patient, and even dryness of the climate, is most interesting, as well as the discussion of LASIK, nomogram refinement from postoperative results.

Section two deals with the instrumentation involved in the LASIK procedure, including speculums, corneal markers, tonometry, forceps and spatulas, as well as irrigation cannulas and antidesiccation chambers (in the rare event of a free flap). A very useful chapter devoted to in-depth discussion of various traditional microkeratomes and their comparative data is presented, along with excellent photographs. A specific chapter on the operation of the Chiron Hansatome and the “down-up” LASIK technique for production of a superior based hinge will be welcomed by both experienced and novice LASIK surgeons alike. This section also contains individual chapters devoted to disposable keratomes including the FLAPmaker (used on a monitored basis as numerous sites worldwide, including the Center for Sight at the Queen Victoria Hospital) and the Hydroblade waterjet microkeratome.

Section three is devoted to the preoperative evaluation of the patient. This is an extremely important topic, which should be read by anyone involved in the care of LASIK patients. To quote Dr Machat, “Managing patient expectations is the pivotal element to creating happy refractive patients”. Additionally, he writes “A surgeon who never has a complication is one who never performs surgery”. Candidate selection, careful screening for pre-existing conditions and anatomical limitations, as well as contraindications for LASIK are thoroughly explored, as is the topic of LASIK as the procedure of choice of patients over the age of 40 is given, but the reality is that few refractive surgeons wish to retreat patients, and as such bilateral LASIK treatment is commonly recommended. This is unfortunate as most patients wish to shed their glasses or their presbyopic
Section four includes seven chapters devoted to detailed descriptions and superb photographic and diagrammatic illustrations of personal LASIK surgical techniques of some of the best LASIK surgeons. This will surely be one of the most valuable sections of the text for surgeons beginning their LASIK practices. Section Five is devoted to the topic of LASIK enhancements, whether for refraction or correction of refractive error, or for complications such as central islands, epithelial ingrowth, flap striae, or flap melt. Section six deals with another critical issue for both the refractive surgeon as well as the co-managing optometrist—namely, the postoperative care of the LASIK patient. Here we have an excellent chapter detailing the specific normal and abnormal responses occurring in the intermediate postoperative period, as well as in the first months after surgery. A wonderful section on corneal topography evaluation is presented, along with an excellent chapter written by co-managing optometrist (Dennis Kennedy, OD), illustrating the role now being played by the healthcare team caring for the patient. The next section presents details of surgical outcomes for LASIK, including studies done at the Emory Vision Correction Center, TLC (The London [Ontario] Laser Center) outcome studies, and the CRS LASIK Study. Two chapters follow, devoted to hyperopic LASIK. Another two deal with LASIK following penetrating keratoplasty, RK, and intracorneal surgery such as phakic IOLs. Section nine is another “must read” for the refractive surgeon, as it includes several chapters with specific treatment techniques for LASIK. The chapters deal with epithelial ingrowth, flap striae, and overcorrection. My one criticism of this section comes only after an editorial viewpoint, in that there is considerable overlap in the topics discussed by the several chapter authors in this section, which could have been streamlined by the editors. However, as with most ocular complications of surgical procedures and/or ocular diseases, there is a variation in clinical treatment detail, even though the basic management principles are likely to be the same. Thus, the reader may appreciate these treatment variances when reading this section. The final section deals with topography assisted LASIK techniques that can be helpful in cases of decentred ablation zones after PRK, irregular astigmatism after PK and RK, and asymmetric corneal astigmatism. In addition, the reader will appreciate the last chapter with the contents of 15 clinical cases involving complex LASIK management.

The Art of LASIK is an outstanding collaborative effort. The editors and contributors are highly experienced, and have greatly expanded our knowledge of this increasingly popular surgical treatment of refractive conditions. Its major strengths lie in its emphasis on careful patient selection and counselling, meticulous preoperative, surgical, and postoperative examinations, and in effective management of complications. The Art of LASIK should be read not only by refractive surgeons, but by all ophthalmic clinicians involved in the care of the refractive surgery patient.

JOEL A. SILBERT
Director, Cornea and Specialty Contact Lens Service, The Eye Institute, Philadelphia, PA, USA

As part of the Basic Bookshelf for Eye Care Professionals series Denise Cunningham’s contribution on clinical ocular photography does exactly what it says and gives a clear, basic explanation of a range of photographic skills and techniques needed to provide an ophthalmic photography service.

Appointed at período in all branches of eye care, subjects covered include basic and scientific photography, ophthalmic photography, external eye, fundus photography, slit lamp photography, and fluorescein angiography with sections on relevant darkroom techniques and photographic organisation.

There are 140 pages including a comprehensive bibliography and useful index. The photographs used to illustrate various viewpoints are excellent and ingeniously devised—for example, the use a photograph of the face with drawings of the pattern of blood vessels held in front of each eye to show orientation. The quality of reproduction in the publication is somewhat lacking, although this is not glossiness and the price reflects this. It is suggested that gaining knowledge of the interpretation of fluorescein angiography, including pattern recognition and association with disease or disorders, will make individuals’ work more stimulating and also make them more valuable to the employer.

This book does not include digital photography of any kind and neither anterior segment fluorescein angiography nor indocyanine green angiography get a mention. However, although the digital age is with us all, a good background awareness of silver based photography as related to ophthalmic photography is still very important, and this publication provides it.

ALISON FARROW

This book is a diagnostic atlas of ophthalmic A and B scans. The diagnostic scanning techniques and labelling formats are described with clarity in the opening chapter. The techniques described are based on those of Karl Osoining, which have been further refined by Sandra Byrne.

B-scans are taken using a dedicated eye scanner with a mechanically rocked single transducer producing a sector format image. The probe is coupled to the open eye with methyl cellulose gel and dedicated eye scanners are much less sensitive than their more modern whole body counterparts, and often operators work on the open eye to avoid a reduction in sensitivity caused by attenuation of sound as it is transmitted through the eyelid.

This atlas contains over 400 diagnostic images, three quarters of which are B-scans. This reflects a shift in stress away from the A mode technique. Each chapter concentrates on different portions of the globe. The resolution and grey scale are images in general poor but, despite this, the authors illustrate some retinal tears and the diagnoses given in the relevant and comprehensive figure legends are correct.

The book does not cover colour flow mapping or spectral Doppler techniques nowadays used routinely to image blood flow. The authors generally attempt to determine blood flow in tumours by flickering of echoes as seen using A mode techniques.

I found this atlas to be a clearly presented and, within the limitations mentioned above, well balanced book. I would recommend it to all those using dedicated eye scanners, and to those starting out in ophthalmic ultrasound.

MARIE RESTORI

This book will, no doubt, sell well. It has a well known editor and many prominent contributors. The book has a high quality feel to it but is let down by the very poor photographic reproduction of many of the photographs taken from preoperative videos. James Davidson (chapter 12) can produce reasonable quality stills. Why can’t the other contributors? Tables and figures, taken from lectures, may look great on screen, but look tacky when incorporated into text. There is no “house style” since some of the chapters have attractive line drawing figures in the text. The lack of style is irritating in a subject where presentation so obviously important. Equally irritating is the endless repetition of some figures.

I found the title a little misleading since several of the chapters, particularly those towards the end of the book, really have very little to do with clear corneal incision. In a relatively small portion of the book actually deals with the incision itself. For the most part what you have is a series of descriptions of “How I do phaco” by a series of well known cataract surgeons, which is fine. Of course, there are lots of other books along the same lines and another would probably not look so attractive.

What would be a catchy title for another of the same? Clear Corneal Lens Surgery? Am I being cynical?

Clear corneal cataract incisions were not practised very widely in the USA before phacoemulsification but many British and quite a few European readers will have been entertained at home with explanations of clear corneal incision through a clear corneal incision and will have become familiar with its many advantages over a corneoscleral incision. Thus, moving from a scleral tunnel to the cornea as they settled into phaco techniques was a natural and welcome step. I thought the chapter on historical background was superficial and lacking the detail which subsequent chapters contained. Expansion could have made a much more fluent presentation by the contributors and would have helped put it in better context.

Reading most of the chapters in the main part of the book I found it difficult to believe I was not reading a formalised version of the authors’ talks on their favourite method of performing cataract surgery. There was a lot of description and opinion but not very much in the way of explanation or justification. This is not the sort of book that one could dip into, and it certainly is not the sort of “cookbook” that could take a beginner through a procedure. Someone trying to identify a technique that would suit his or her personal style would have to work quite hard to get what was wanted. The information is there but there is a great deal of repetition in the process.

www.bjophthalmol.com
CD ROM REVIEW

This is one of a series of CD ROMs on international health produced by the Wellcome Trust. The series was originally planned as a replacement when the trust closed its museum of tropical medicine more than 10 years ago, and has been a long time in gestation. The available software has come a long way in the past 10 years, and we have come to expect a degree of user friendliness that enables a computer illiterate such as myself to gain easy access to the material; but unfortunately this CD ROM did not come up to my expectations in this respect. It was only after some frustration and considerable help from my wife that I was able to get hold of the main menu. The menu revealed that the material was arranged in three main scenarios: a glossary, an image library, and a tutorial. The glossary is very broad and covers a wide variety of ophthalmological terms that bear no relation to trachoma. The image library is extensive, but includes a large number of pictures of Chlamydia trachomatis at various stages of its life cycle in tissue culture; it is hard to see that these will be relevant to most users with an interest in trachoma who are unlikely to have access to tissue culture facilities. The other unfortunate, but undeniable fact is that all images are of very poor quality when viewed on standard PCs, whether desktop or laptop. I tried both, but the images were at best of advanced cartoon standard. The tutorial was well written and well planned, but also suffered seriously from the poor quality of the images; it would not be possible to learn how to diagnose or grade trachoma with images such as these.

In conclusion, given the choice, I would prefer a simple manual written on paper, which would be more easily accessible, and considerably more informative than this expensive produced CD ROM.

DAVID MABEY
