Age related macular disease

Editor,—I am a retired doctor who suffers from the wet form of age related macular disease (ARMD) in both eyes. In the triangle of doctor, patient, and ARMD what are the implications for one of the key role holders, the ophthalmologists? Is there any longer a place for the phrase oft used by them “I am sorry I can do nothing further for you”?

There is in fact a lot doctors can do both in practical terms and in more subtle shifts of attitudes and behaviour. For example, general practitioners often admit they know little of the disease and may refer a case which requires an early opinion through the usual channels, which may take weeks. Opticians may not refer at all when necessary. Who better to educate and remedy these deficiencies than the experts, the ophthalmologists. Likewise, much needed low vision clinics are more likely to be achieved if promoted by a consultant rather than by a pressure group of patients. Or a rethink on how to make the loss of eyesight more easily interpreted to patients. Or a rethink on how to make the loss of eyesight more easily interpreted to patients. Or a rethink on how to make the loss of eyesight more easily interpreted to patients. Or a rethink on how to make the loss of eyesight more easily interpreted to patients.

No general surgeon or physician nowadays would use such chilling words to a patient with a terminal or degenerative condition.

It has been said that everyone in the health service including patients is a manager. Do all doctors realise the word manager also applies to them? Is there still a feeling among ophthalmologists that they continue to live in the halcyon days when being a doctor meant solely medical practice? We hear today “small” things—meaning—present criteria are primarily geared to use by professionals. Or an explanation that being registered blind has a different connotation from being totally blind and so on.

General surgeon or physician nowadays would use such chilling words to a patient with a terminal or degenerative condition.

Randomised controlled trial of corticosteroid regimens in endothelial cornal allograft rejection

Editor,—In the abstract of their paper Hude et al conclude that “In treatment of graft rejection, additional systemic treatment with 500 mg of methylprednisolone yields no significant benefit over intensive local corticosteroids alone.”

The authors based their statement on the findings that a first episode of endothelial graft rejection could not be reversed in three of 19 patients (16%) treated with local steroids alone, while none of 17 failed to reverse when given additional systemic steroid.

Even though the benefit of the additional steroid therapy may not have been statistically significant because of the small numbers, there is no indication that with larger numbers it might not very well become significant. The authors did not, however, limit their dismissal to a lack of statistical significance of the outcome, but broadened it to the wider summary statement of “no significant benefit”. Their clinical efficacy is such a sweeping condemnation. Reversal of the first graft rejection episode without a single failure in 17 patients would certainly strengthen a clinical argument in favour of additional treatment with systemic steroids.

The authors do themselves admit that the statistical power of the study was such that it would only have been able to detect a difference in outcome of the order of 40%. Do they then reason that a difference in outcome of less than 40% is to be regarded as clinically irrelevant? Why was such an arbitrary statistical straightjacket chosen for this study?

Considering that those effects of the systemic steroid treatment were observed, I regard the outcome of the study of clinical relevance, particularly since an increased cure rate of the first (and possibly successive) rejection episode would affect the long term outcome of these grafts.

In my opinion, this study does not disprove the efficacy of additional systemic steroid treatment for initial episodes of graft rejection.

Indocyanine green guided laser photoocoagulation in patients with occult choroidal neovascularisation

Editor,—I read with interest the paper by Weinberger et al.1 In this pilot study about ICGA guided photoocoagulation of occult choroidal neovascularisation (CNV) in AMD, the authors provide evidence for a beneficial effect on visual prognosis by treating this CNV pattern. However, some inferences can be raised about both inclusion criteria and patients’ selection and then about results.

On ICGA, all eyes included in the study show a choroidal neovascular network, with CNV size smaller than four disc diameters (the authors do not specify how many hot spots, plagues, or mixed lesions are in their sample). Indications for treatment, visual prognosis, and recurrence rate in these three CNV morphological types are quite different.2

Furthermore, a marked disproportion between eyes with pigment epithelial detachment (PED) (two cases) and those without PED (the remaining 19), reflecting the data provided by Guyer and colleagues in 1000 consecutive eyes,3 characterises the examined population. The authors present the final anatomical and visual outcomes by considering all eyes as a single group; this method is questionable, since vascularised PED and RPE are definitely two distinct entities. Occult CNV with PED has a higher frequency of recurrence, probably due to the greater exudative activity of primary PED and, even if anatomical outcome of laser photocoagulation is satisfactory, the functional result is usually poor.4 Then the encouraging final visual acuity reported in the paper is probably biased by an anomaly in sample composition and by improper grouping.

In order to draw definite conclusions and provide guidelines about ICGA guided laser treatment of occult CNV, there is a clear need for a randomised prospective, controlled clinical trial, with a larger population and a more realistic proportion between occult CNV with and without PED, and presenting separate final results for the two patterns with regard to both anatomical and visual variables.

Reply

EDITOR.—We thank Dr Da Pozzo for his inter-
est in our paper. He raised a number of inter-
esting points.

Patient selection for ICG guided laser photo-
ocoagulation is extremely crucial. Functional results from different pilot studies on ICG guided laser photoocoagulation show various outcomes. This may be explained either by the patient selection or by the indications for ICG guided treatment. Especially, the de
nition of choroidal neovascular network in ICG angiograms is crucial since the inter-
pretation of ICG angiograms is still under discus-
sion.

Our interpretation of ICG angiograms for the detection of a CNV is based on the choroidal transit and recirculation phase of ICG dye recorded with a scanning laser ophthal-
microscope. We consider this to be more accurate in determining the size, location, and geometry of CNV than the late phase. We have demonstrated that occult CNV de

ned by the MPS standards could be converted into visible neovascular membranes in up to 50% of cases cases of the presence of PED. Using other imaging techniques, hot spots and plaque hyperfluorescence were used to convert occult CNV into visible CNV. Previous studies on ICG guided laser photoocoagulation rely almost exclusively on this interpretation of ICG angiograms. However, it has recently been demonstrated that many eyes with hot spots in late ICG angiograms have polypoidal choroidal vasculopathy (PCV). Since previous studies did not differentiate between eyes with PCV and AMD, a quite significant proportion of eyes included in these studies may have had PCV instead of AMD (Slakter 1999, personal com-
munication). This may have influnced their findings, since it is important to differentiate AMD from PCV because there are significant differences in the demographic risk profile, natural course, visual prognosis, and manage-
ment of these patients.

Our study involved 175 consecutive pa-

tients undergoing ICG angiography for occult CNV secondary to AMD. We performed ICG guided laser photoocoagulation only in eyes with occult CNV that demonstrated a visible exudative or subfoveal neovascular network in the early ICG angiogram. In these eyes no hot spots or plaque hyperfluorescence were detected in the late angiograms. Only two eyes with PED were included in the study accord-

ing to the inclusion criteria. This small number allowed no subgroup analysis. How-

ever, by analysing the 19 eyes without PED the results are even more promising.

We are aware that the eyes included in our pilot study may represent a special subgroup of eyes with occult CNV as pointed out in the original manuscript. Additionally, this is well demonstrated by the small number of patients included in the study. However, reviewing our quite encouraging final visual results we feel very comfortable with ICG guided laser photoocoagulation following our interpretation of ICG angiograms in occult CNV secondary to AMD.

We totally agree that there is a clear need for a randomised prospective, controlled clinical trial to prove the efficacy of ICG guided laser photoocoagulation for ICG-guided laser treatment. Especially, the de
nition of choroidal neovascular network in ICG angiograms is crucial since the inter-
pretation of ICG angiograms is still under discus-
sion.

Phacoemulsification combined with silicone oil removal through posterior capsulorhexis

EDITOR.—We read with interest the report by Fra
er et al. and noted that our recent article in Ophthalmology was not cited as a reference.1 In this article we reported our experience at Moorfields Eye Hospital with 34 eyes pros-
ppectively evaluated to look at the efficacy and potential complications of combined cataract extraction and silicone oil removal with poste-
rerior chamber lens implantation. We also reported the method of Restori, ophthalmic ultrasound specialist at Moorfields Eye Hospi-
tal, for calculating the IOL power in an oil filled eye with correction for the specific grav-
ity of silicone oil taken into consideration. Our findings were that the procedure was safe and effective for these eyes that had often had many previous surgeries. The visual outcome in these eyes was generally good with improve-
ment in visual acuity, even with recurrent reti-
nacular detachment or pre-existent macular pa-
thology. We also concluded that it was safer to place a rigid posterior chamber implant after silicone oil removal due to potential contrac-
tion of the posterior capsule limiting the view of the retina postoperatively. Our technique was a passive technique but might easily be done with the I/A handpiece as this group reported.

We feel that it would have been appropriate for them to make reference to our study since it presents a much larger series with more detailed follow up.

Susceptibility to ocular autoimmune disease

EDITOR.—We read with interest the Newsdesk piece in the March 2000 issue of the BJOC, commenting on recent studies indicating a conceptual shift in the understanding of the molecular basis of differential susceptibility to organ specific autoimmune diseases. How-

ever, we were disappointed to see that the News-
desk piece was restricted to studies of the animal model of multiple sclerosis and not that of uveitis. In a paper published in 1997 we dem-

onstrated that ocular specific antigens (S-

antigen (arrestin) and interphotoreceptor reti-

noid binding protein (IRBP)), which are targets for pathogenic autoimmune processes, are expressed in the thymus of certain animals. Furthermore, we found that animals which express S-antigen or IRBP in their thy-
mus are resistant to experimental autoim-

mune uveoretinitis induced by the corre-

sponding molecule, whereas the absence of thymic expression correlates with susceptibil-

ity.
