Tears and conjunctival scrapings for coronavirus in patients with SARS

Severe acute respiratory syndrome (SARS) was first recognised in Guangdong Province in China and later in Hong Kong in March 2003.1 Within a matter of weeks, the outbreak has evolved to become a global health threat and almost 30 countries have been afflicted with the novel coronavirus strain (SARS-CoV).2 SARS is a highly contagious potentially lethal disease. The main route of transmission is by respiratory droplets, though the virus has also been isolated in stool and in urine. Tears, being one of the body fluids, may potentially harbour the virus. The presence of viruses in these body fluids may affect our precaution practices and sites of sampling for diagnostic tests.

Case series

A prospective interventional case series study was conducted on the identification of the SARS-CoV virus in tear secretions and conjunctival samples of patients with confirmed SARS. Approval was obtained from the ethics committee of the Chinese University of Hong Kong. Consecutive patients with probable SARS in the Prince of Wales Hospital, Hong Kong, during the epidemic period from April to May 2003 were recruited. Other than the routine samples of nasopharyngeal, mouthwash and stool, tear swab and conjunctival scraping were taken randomly from one eye of all recruited patients. The tear swab was taken by putting a sterile cottonwool stick into the deep lower fornix of each patient’s eye after a single drop of topical anaesthetic agent (1% atemocaine eye drops) was applied. Conjunctival scraping was performed at the lower palpebral conjunctiva with a bent tip of a sterile 23 gauge needle. All ocular samples were collected by a single ophthalmologist with personal protective equipment recommended by the infection control unit of the hospital. Particular care was taken not to contaminate the samples.

The samples were analysed by virus culture and RT-PCR. The SARS-CoV specific primers COR-1 (sense) 5’-CAC GTT TTC TAG AGG TTA GCT AAC GA 3’ and COR-2 (antisense) 5’-AAA TGT TTA CGC AGG TAA GGG TAA AA 3’ were used to detect the presence of SARS-CoV RNA.4 All the patients were further categorised as confirmed SARS with a seroconversion or fourfold increase in antibody titre. The antibody against coronavirus was detected by indirect immunofluorescent technique based on Vero cells infected with SARS-CoV isolated from a patient with SARS.5 A total of 20 probable SARS patients were recruited and 17 were later confirmed with paired convalescent sera. Among the confirmed cases, the mean age was 40.5 (SD 8.8) years and 12 (70.6%) were female. They were recruited during the first (n = 6, 35.3%), second (n = 8, 47.1%), and third (n = 3, 17.6%) waves of their diseases. Five (29.4%) of the 17 patients were positive for SARS-CoV by PCR with the samples from nasopharynx or stool (table 1). In all tear and conjunctival scraping samples, no SARS-CoV virus could be detected by RT-PCR or isolated by viral culture. Apart from two patients having mild and self limiting conjunctival bleeding after scrapings, no other ophthalmic complication was reported.

Comment

The routes of transmission of SARS other than respiratory droplets and stool are still enigmatic. In fact, tears have been reported by the World Health Organization to be one of the body fluids that might convey the novel SARS coronavirus, though the infectivity or clinical significance is not known.6 The negative findings of SARS-CoV viral genetic material or viable virus in the tear secretion or conjunctival cells of patients with serologically confirmed SARS may have several interpretations. Firstly, RT-PCR testing or viral culture is known to be very specific but lacks sensitivity. Peiris and colleagues reported that only 22 of 44 (50.0%) nasopharyngeal aspirate samples and 10 of 18 (55.6%) faecal samples from patients confirmed with SARS had coronavirus genetic material detected by RT-PCR.6 So negative test results can be false negative and do not exclude the presence of the virus. Sensitivity can be increased if multiple specimens are tested. Secondly, it is possible that the virus and its genetic material were only present for a brief period of the disease, and the samples were not collected at the right time. Thirdly, the virus might not be present in tears at all.

The limitations of this study are the relatively small sample size and only the fact that one sample of tear swab and conjunctival scraping were taken from each patient. We cannot totally exclude the presence of SARS-CoV in the tear secretion, but it is clear that conjunctival swabs and conjunctival scrapings are not useful samples for confirming or excluding the diagnosis.

Congenital third nerve palsy in septo-optic dysplasia

Paediatric ocularmotor nerve palsies are rare lesions. The most frequently cited mechanism is perinatal injury to the peripheral third nerve, although they may be due to congenital absence of the nerve and/or nucleus and be accompanied by neurological deficits. *Septo-optic dysplasia consists of optic hypoplasia, mid-brain malformations, and hypothalamohypophyseal dysfunction.* We present three children with congenital third nerve palsy and septo-optic dysplasia.

Case reports

We report on three children with bilateral optic nerve hypoplasia, with visual function from light projection to 0.05 and nystagmus. Magnetic resonance imaging revealed absent septum pellucidum, thinning of corpus callosum, and posterior pituitary ectopia in two cases and infundibular hypoplasia in the third case. They had anterior pituitary hormone deficiency—growth hormone, adrenocorticotropic hormone, and hypothaloidism in case one and two, with additional diabetes insipidus in the third case. There were no other associated brain or ocular anomalies. These children had no positive history of perinatal trauma, drugs, or toxic agents. There was no history of parental consanguinity.

Case 1: unilateral, left, pupil-sparing third nerve palsy, with fixed exodeviation of 45 prism dioptres and hypotropia of 30 prism dioptres, no ptosis, anisocoria, or aberrant regeneration of the oculomotor nerve. The third case was brought to our attention immediately after birth with bilateral third nerve palsy and pupil involvement on the left side (figs 1 and 2). Orthoptic examination revealed bilateral defective medial gaze and elevation and defective depression on the left side. In course of the first year of life pupillary reaction recovered without aberrant regeneration. At the age of 12 years the child died during febrile illness.

Comment

Our three children with septo-optic dysplasia had unilateral congenital third nerve palsy in two cases and bilateral palsy in one case.

There was no ptosis and no involvement of the contralateral superior rectus muscle in the two patients with unilateral nerve dysfunction, indicative perhaps of peripheral nerve defect. A possible explanation for the lack of aberrant regeneration may be due to extreme atrophy or even absence of the third nerve. The child with unilateral third nerve palsy (case 3) had postnatal pupillary involvement in one eye, with regeneration within 1 year. Peripheral nerve damage as well as nuclear defects may have been responsible. Previous reviews in the literature showed that several kinds of brain damage could result in congenital ocularmotor palsies, such as brainstem infarction, cerebellar and midbrain hypoplasia, absence of basilar ganglia, etc.

Two theories have been proposed regarding the pathogenesis of septo-optic dysplasia. As all affected components arise from different tissues and processes at different times developmental anomaly or dysplasia makes little embryological sense. Genetic causes are exceptional. A vascular disruptive sequence similar to porencephaly, possibly involving the proximal trunk of the anterior cerebral artery is discussed by Lubinsky.

Our findings of congenital third nerve palsy in de Morsier syndrome do not support this hypothesis, as the third cranial nerve and its nuclei are not within the territorial distribution of the anterior cerebral artery and there were no additional defects in the median and paramedian areas of the frontal lobes. The partial palsy in case two, with some amount of adduction, elevation, and depression and the recovery of the pupillary involvement in case three implicate probably prenatal traumatic, infectious or toxic insults, thus supporting the theory of secondary degeneration.

Penetrating eye injury from rear view mirrors

Penetrating eye injuries are a common complication of severe motor vehicle accidents. The majority of cases accompany facial laceration when the head of a front seat occupant passes forward, and then back, through the broken windshield. The frequency of such injuries has been greatly reduced since legislation was introduced to make the wearing of seatbelts for all occupants and the use of laminated windshield glass compulsory. Glass entering the car through an open side window from a broken external rear view mirror is an uncommon but potentially preventable cause of severe ocular injury. First reported in 1990 by Keenan,* there have been two subsequent reports from Australia. We report two further cases and highlight deficiencies in legislation regarding the manufacture of external rear view mirrors.

Case reports

Case 1

A 17-year-old man was driving a 1987 registered Fiat Uno when the driver’s external rear view mirror struck an oncoming van. The mirror broke and a fragment of glass passed through the open side window and hit his left eye. He sustained a corneal and scleral laceration but the lens and iris were not damaged. Following primary repair he made an uneventful postoperative recovery and retained a corrected visual acuity of 6/9 with spectacles.

Case 2

A 22-year-old woman passenger of a 2002 registered Peugeot 206 was struck in the right eye when the side mirror struck the mirror of a parked car. The mirror was broken and a fragment of glass entered her right eye through the open passenger window. She sustained a large corneal and scleral laceration with loss of the majority of the iris and damage to the lens. She underwent primary repair of the laceration with lens aspiration and anterior vitrectomy. She subsequently required a second vitrectomy with gas injection for vitreous gel incarceration and a retinal tear. She regained a visual acuity of 6/24 with a contact lens correction, but further improvement was prevented by corneal scar.
Comment

Broken rear view mirrors have previously been identified as a cause of severe ocular injuries. The two cases we describe occurred in similar circumstances and both patients sustained penetrating eye injuries caused by glass from the broken external rear view mirror entering the car through an open window. The external rear view mirrors project beyond the body of the car and in both cases the mirror was broken following a collision with another vehicle in which the wing mirrors were clipped. No other vehicle damage occurred.

All exterior rear view mirrors fitted to cars in the United Kingdom have to comply with the European Community Directive 71/127/EEC which was last amended in 1988 (Directive 88/321). This requires mirrors designed for use in cars to undergo a “pendulum test” using a 7 kg weight on a pendulum of 1 metre length released at a 60 degree angle from the vertical to represent the impact of a head hitting the mirror. The test is performed with the weight hitting both the reflecting surface side and repeated on the opposite surface. If, at the end of this test, the glass of the mirror breaks, any fragments should adhere to the back of the protective housing. However, the directive further specifies that:

1. Partial unsticking of the glass is permitted provided that this does not exceed 2.4 mm either side of the cracks. This is acceptable for small shards to detach themselves from the surface of the glass at the point of impact.
2. The reflecting surface shall be made of safety glass.

It is therefore permissible for small splinters of glass to become detached from the surface of the glass at the point of impact, which is the case for any automobile safety glass. However, in both our cases the fragments appear to have been released from the mirror by spalling following a relatively high velocity impact on the reverse of the mirror housing. The released glass fragments had sufficient momentum to pass through the open window of the car and penetrate the eye. The test described above simulates an object striking the mirror at a velocity of 3.1 m s⁻¹ when the mirror of a car travelling at 30 miles per hour hits a stationary object. This velocity would be considerably higher if the car mirror clipped an oncoming car.

These cases highlight that there is a continuing risk of severe eye injury following an impact on the back surface of an external rear view mirror. Current legislation is based on a test that does not replicate the most probable circumstance of impact or the associated risk to the eye. The test is based on the effect of a low velocity impact, as opposed to the high velocity impact that would result from two cars passing in opposing directions. Replacing the glass with plastic would be an option to reduce the risk, although current plastic surfaces do not have the resistance to abrasion of glass which could result in scratches causing distracting light reflections. Avoiding driving with the side windows down, or repositioning the external mirrors are further options.

Coats’ disease in a vegetarian female

Coats’ disease is an idiopathic condition characterised by telangiectatic and aneurysmal retinal vessels changes with intraretinal and subretinal exudates. Here we report one case of a young female with an unusual manifestation of Coats’ disease.

Case report

A 14 year old female was referred for loss of vision in the left eye of a few weeks’ duration. The referring ophthalmologist thought the patient had a choriotetral inflammatory process with secondary exudative retinal detachment and had recommended a complete medical examination for choriotetinitis.

Visual acuity was 20/20 right eye and 20/400 left eye. Anterior segment examination was normal in both eyes. There were no cells or flare in the anterior chamber and in the anterior vitreous in either eye. Posterior fundus examination of the right eye was normal. In the left eye there was an exudative, neurosensory macular detachment and intraretinal lipid exudation temporally (fig 1A), leading to an area of microvascular changes in the peripheral retina (fig 1B). There was capillary non-perfusion, dilation and beading of the larger vessels, aneurysmal and telangiectasia formation. There were also telangiectatic vascular changes and intraretinal leakage of fluorescein dye throughout the peripheral fundus. The patient was diagnosed with Coats’ disease, even if the clinical presentation was somewhat unusual for Coats’ disease, given the absence of massive intra-retinal and subretinal lipid exudation. A complete medical examination inclusive of PPD, chest x-ray, lime titre, Bartonella titre, FTA-abs, VDRL, ACE level, CBC with differential, was negative. The patient had been an absolute vegetarian from birth; her cholesterol level was 116, and her triglyceride level was 83.

Scatter laser photoagulation was applied around the area of telangiectatic retinal changes and in the temporal retina. Six months later the vision was improved to 20/100. There was partial resolution of the exudative, neurosensory retinal detachment and more lipid deposition in the macula.

There was also new occurrence of preretinal neovascularisation and vitreous haemorrhage (fig 2A, B). Further scatter photoagulation was applied to the temporal retina. One year after the original presentation the vision in the left eye had improved to 20/40. There was complete resolution of the exudative neurosensory detachment both in the macula and in the inferior periphery. The lipid exudation in the macula had mostly reabsorbed. There was also total regression of the preretinal neovascularisation in the temporal periphery (fig 2C, D). There was also complete resolution of the microvascular telangiectatic changes and intraretinal leakage both in the temporal retina, which had been treated with scattered laser photoagulation and in the nasal retina, which had received no treatment.

Comment

This is an unusual manifestation of Coats’ disease because of the limited intraretinal lipid exudation. A possibility is that the reduced lipid exudation was related to the fact that the patient was totally vegetarian with very low cholesterol and triglyceride levels.
Churg-Strauss syndrome in a child: retina and optic nerve findings

Allergic granulomatosis and angiitis, also known as Churg-Strauss syndrome (CSS) is predominantly a disease of adults. It is rare in children. We present a case of CSS in a young child that resulted in bilateral optic neuropathy with vasculitis and multiple branch retinal artery occlusions affecting the macula.

Case report

A 10-year-old African-American girl developed sudden painless loss of vision in both eyes over 2 days. The child was an inpatient admitted for examination of a multisystem disorder, affecting her pulmonary, gastrointestinal, muscular, and renal systems. On examination the best corrected vision was hand movement in both eyes. Confrontational visual fields were full. Pupils were normal, without an afferent papillary defect. Anterior segment examination was completely normal. Posterior segment examination revealed marked retinal opacities in the macular region (fig 2). There was also pruning and non-perfusion of both small retinal capillaries and choroidal vessels. The retinal arterioles venules demonstrated staining and leakage. Both optic discs were stained with fluorescein.

Fluorescein angiography demonstrated bilateral blocking defect caused by retinal opacification and haemorrhages and non-perfusion in the macular region (fig 2). There was also pruning and non-perfusion of both small retinal capillaries and choroidal vessels. The retinal arterioles venules demonstrated staining and leakage. Both optic discs were stained with fluorescein.

The patient had patchy pneumonitis and asthma, hypertension, acute renal failure, elevated liver enzymes, and eosinophilia of greater than 40%. Renal biopsy showed non-specific glomerular inflammation, but no eosinophilic infiltration or granulomata. A magnetic resonance image of the liver showed no involvement.

levels. The development of preretinal neovascularisation in the temporal periphery was also unusual. We thought that it was secondary to retinal ischaemia and not a break in Bruch’s membrane after laser photocoagulation. We also found interesting the fact that the scatter photocoagulation of the temporal periphery resulted in regression of the microvascular telangiectatic changes both in the area that had received laser treatment and in the nasal periphery that had received no treatment. As expected, scatter laser photocoagulation resulted also in reduction of the lipid exudates, similar to what has been described in diabetic retinopathy.

parenchymal damage. An infectious examination was negative for tuberculosis, Lyme, cat scratch disease, syphilis, HIV, cytomegalovirus, Epstein-Barr virus, toxoplasmosis, or toxocariasis. An oncological examination was negative. ANA, anti-dsDNA, ANCA, complement levels C3, C4, and CH50 were all normal. The diagnosis of Churg-Strauss syndrome was made based on three of six criteria advanced by the American College of Rheumatology,1 which include asthma, hyperesinophilia of >10%, non-fixed pulmonary infiltrates.

The patient was started on high dose intravenous steroids (2 mg/kg/day) and cyclophosphamide. Intravitreal triamcinolone acetomide injection was performed in the right eye with improvement of macular oedema. However, the vision remained no better than 20/400 in both eyes at 1 month.

Comment

CSS is a systemic granulomatous necrotising vasculitis affecting small to medium-sized vessels. Takanashi et al6 classified ocular manifestations into two groups: pseudotumour-type and ischaemic vasculitis-type.6,8 Pure ischaemic vasculitis-type manifestations were associated with a sudden onset loss of vision, a quiet looking eye, lack of computed tomography (CT) abnormalities, and a positive ANCA.6 In contrast, pseudotumour-like manifestations involved a chronic onset, a red eye, orbital abnormalities on CT, and a negative ANCA.6 Takanashi et al advised that patients with positive ANCA CSS, who are visually asymptomatic, be carefully examined and treated prophylactically with high dose steroids in order to prevent potentially irreversible visual loss from the ischaemic-type ocular manifestations.9 The devastating loss of vision in this child with ANCA negative CSS suggests that all patients with CSS should be considered for prophylactic high dose corticosteroids, regardless of their ANCA status.

The histological appearance of the poorly differentiated squamous carcinoma within dense fibrous tissue in the orbital biopsy (magnification ×400, haematoxylin and eosin).

the presence of metastasis suspected, the symptoms of dysphagia led to further investigation and demonstration of an oesophageal primary carcinoma. (The oesophageal biopsy was done 10 days after the orbital biopsy). The most likely neoplasms to metastasise to the orbit include carcinoma of the lung, breast, and prostate. The orbital tumours may be located anywhere in the orbit but presentation as a lacrimal gland tumour is unusual.

Gastrointestinal carcinoma with metastasis to the orbit represents approximately 6%–7% of reported cases. These include carcinoma from stomach, ileum, and colon.

Only one report describes a metastatic oesophageal carcinoma to the intracranial orbit, but in this case, the clinicians were aware of the oesophageal disease before the occurrence of the orbital tumour.

As far as we know, our case is the first report of a silent carcinoma of the middle third of the oesophagus presenting as a lacrimal gland neoplasm and the case reiterates the importance of careful history-taking and thorough preoperative assessment.

Vitreoretinal abnormalities in the Conradi-Hunermann form of chondrodysplasia punctata

Autosomal dominant chondrodysplasia punctata or Conradi-Hunermann disease is a rare disorder with variable expressivity. It is characterised by dysplastic skeletal changes with premature punctate epiphysial and paravertebral calcification, associated with moderate growth deficiency, scoliosis, limb asymmetry, flexion contractures of the hips, knees and elbows, talipes equinovarus, short neck, frontal bossing, nasal bone hypoplasia with characteristic “koala” facies and dystrophic changes in hair and skin. Among the ocular features reported, cataracts are by far the most common, occurring in about 20% of cases of Conradi-Hunermann disease compared with a much higher incidence (>66%) in the more severe (and usually lethal) autosomal recessive and X linked dominant forms of the disease. In addition, optic atrophy, microphthalmos, iris hypoplasia, and Axenfeld-Rieger syndrome have been described.

Case report

We describe unusual vitreoretinal abnormalities in a 28 year old woman with Conradi-Hunermann disease. Her original diagnosis had been made in childhood based on clinical and radiological grounds, and she had undergone numerous cosmetic and reconstructive procedures on her nose, jaw, and lower limbs, as well as right cataract surgery at the age of 18 years for cortical lens opacity. Refraction showed low hyperopia and her left eye, also affected by cataract, had been considered amblyopic. She presented to us with a short history of photopsia and floaters in the left eye, but with no change to her corrected Snellen visual acuities of 6/12 right and 6/36 left. Anterior segment examination revealed lower lid distichiasis and quiet pseudophakia on the right, and peripheral cortical lens opacities and a small pupil on the left. Her intraocular pressures were normal. Funduscopy showed healthy discs and maculae, with temporal dragging of vessels on the right (as had been noted many years previously). No posterior vitreous detachment was evident in either eye, but a number of unusual vitreoretinal tractional complexes were present, more marked on the left, with underlying retinal pigment epithelium disturbance (fig 1). The fundal view on the left was impaired by the cortical cataract and small pupil.

Strands of condensed vitreous emanated from each complex, pulling partial and full thickness opercula. The right eye showed flatter complexes, which appeared more stable, with less traction. In the left eye the precise nature of some of the tractional complexes was difficult to ascertain because of the cortical cataract and small pupil; it was uncertain whether they represented retinal schisis or full thickness combined tractional and rhegmatogenous lesions. A

Comment

We describe previously unreported vitreoretinal abnormalities in a patient with Conradi-Hunermann disease. The pathogenesis of these lesions is not understood, but it may not be surprising that yet another skeletal dysplasia is associated with vitreoretinal changes. Identification of the underlying genetic defect in this particular variant of chondrodysplasia punctata may provide insight into the development of both bone and vitreous. We hope that better reporting of vitreoretinal features in Conradi-Hunermann syndrome will help improve understanding and management of this condition.

“Imploding antrum” or silent sinus syndrome following naso-tracheal intubation

Silent sinus syndrome is a condition in which chronic asymptomatic maxillary sinus disease presents with spontaneous unilateral enophthalmos and hypoglobus. Patients have inferior displacement of the orbit due to a downward bowing of the orbital floor and atelectasis of the maxillary antrum. Although the underlying maxillary sinus pathology is “silent”, it has been suggested recently that “imploding antrum” more closely describes the acute nature of maxillary sinus collapse that occurs in the majority of cases. We present a typical case that appears to have been related to previous naso-tracheal intubation.

Case report

A 27 year old woman was referred to ophthalmology outpatient complaining that her left eye was lower than the right and that when she looked down, she could see more of her left cheek than on the other side. She had started to notice this following an admission to hospital 6 months previously with viral meningitis. Since then, she had also experienced a “heavy blocked” feeling in the left side of her face together with some left nasal congestion. There was no history of acute sinusitis or chronic rhinosinusitis and, in particular, no history of trauma or surgery to the face—although she had had a naso-tracheal intubation for a routine general anaesthetic 1 year earlier.

On examination, she had normal visual acuity and extraocular movements, but was found to have 2 mm of enophthalmos and 2 mm of hypoglobus. On subsequent review in the ENT clinic, nasendoscopy revealed a left deviated nasal septum with obstruction.

Figure 1 Coronal magnetic resonance image showing opacification and marked reduction in volume of the left maxillary sinus.

Figure 1 Vitreoretinal abnormalities in chondrodysplasia punctata. Retinal drawing with photographic insets of the left fundus, illustrating the nature and distribution of the vitreoretinal tractional complexes described. Vitreous condensations emanating from each complex can be seen, but the partial and full thickness ovoids are difficult to appreciate in the photographs because of cortical cataract and small pupil. The right fundus is not shown here but had similar lesions, only less florid.

Figure 1

Group of three such lesions was located just temporal to the macula in the left eye. Given the unstable appearance and symptomatic nature of the left eye, the tractional lesions associated with retinal breaks were treated by argon laser retinopexy. One of the three temporal tractional complexes was treatable with laser because of the cortical lens opacity.

Two weeks later the patient noticed a nasal visual field disturbance associated with photopsia in the left eye. She had developed a partial posterior vitreous detachment with a temporal rhegmatogenous retinal detachment transecting the macula, secondary to breaks associated with the temporal tractional complexes. She subsequently underwent left phacoemulsification, intraocular lens implantation, pars plana vitrectomy, encirclement, endolaser, cryotherapy, and C3F8 gas injection. During the surgery the condensed vitreous was found to be very adherent to the tractional complexes; multiple retinal breaks opened up within the complexes and also in a few areas of apparently “normal” retina. Postoperatively the retina was flat, but she developed raised intraocular pressure associated with a fibrous anterior uveitis and iris bombe—this settled with topical therapy and Nd:YAG laser peripheral iridotomy. Six weeks later an inferotemporal retinal detachment secondary to proliferative vitreoretinopathy occurred. This was treated successfully by membrane peel, endolaser, and gas tamponade. Her retina has remained flat since, with a Snellen visual acuity of 6/36 in this left amblyopic eye.

‘Imploding antrum’ or silent sinus syndrome following naso-tracheal intubation

Silent sinus syndrome is a condition in which chronic asymptomatic maxillary sinus disease presents with spontaneous unilateral enophthalmos and hypoglobus. Patients have inferior displacement of the orbit due to a downward bowing of the orbital floor and atelectasis of the maxillary antrum. Although the underlying maxillary sinus pathology is “silent”, it has been suggested recently that “imploding antrum” more closely describes the acute nature of maxillary sinus collapse that occurs in the majority of cases. We present a typical case that appears to have been related to previous naso-tracheal intubation.

Case report

A 27 year old woman was referred to ophthalmology outpatient complaining that her left eye was lower than the right and that when she looked down, she could see more of her left cheek than on the other side. She had started to notice this following an admission to hospital 6 months previously with viral meningitis. Since then, she had also experienced a “heavy blocked” feeling in the left side of her face together with some left nasal congestion. There was no history of acute sinusitis or chronic rhinosinusitis and, in particular, no history of trauma or surgery to the face—although she had had a naso-tracheal intubation for a routine general anaesthetic 1 year earlier.

On examination, she had normal visual acuity and extraocular movements, but was found to have 2 mm of enophthalmos and 2 mm of hypoglobus. On subsequent review in the ENT clinic, nasendoscopy revealed a left deviated nasal septum with obstruction.

Figure 1 Coronal magnetic resonance image showing opacification and marked reduction in volume of the left maxillary sinus.
of the middle meatus, while the middle turbinate could not be visualised.

Magnetic resonance imaging clearly showed depression of the left orbit with thinning of the orbital floor and a marked reduction in maxillary sinus volume (fig 1). The maxillary antrum was opacified and the middle turbinate severely latera lised. The ethmoid, frontal, and sphenoid sinuses were clear.

She underwent septoplasty and functional endoscopic sinus surgery (FESS) during which a left middle meatal antrostomy was performed. Biopsies from the antrum demonstrated polyoid fibrous and mucoid material with no viable cellular tissue. Bacterial and fungal cultures were negative.

At follow up she had reduced hypoglossus of the left eye, an improvement in the left nasal airway and resolution of facial pressure. Orbital floor reconstruction was not required.

Comment
Silent sinus syndrome generally occurs in the third to fifth decade, shows equal sex distribution, and presents with anything from acute or chronic sinusitis and no previous pressure. Other symptoms can include transient distribution, and presents with anything nasal airway and resolution of facial pressure. The silent sinus syndrome. A cause of spontaneous enophthalmos. Ophthalmology 1994;101:772–8.

No association of p53 codon 72 and p21 codon 31 polymorphisms in Taiwan Chinese patients with pterygium

After abnormal expression of the p53 gene being found in epithelium, pterygium is now considered to be a result of uncontrolled cell proliferation, like a tumour.1 4 The p53 gene is a tumour suppressor gene, whose function is mediated by stimulation of p21 (Waf-1) gene. Another tumour suppressor gene, to control cell cycle and prevent tumour formation.1 Mutations in either p53 or p21 are detected in many tumour cells,1 4 and polymorphisms of p53 codon 72 or p21 codon 31 were found to be associated with many tumours.1 4

Because of the abnormal expression of the p53 gene in pterygium epithelium1 7 and there is evidence that hereditary factors may have a role in the development of pterygium,1 4 it is logical to suspect the correlation between pterygium formation and p53 and p21 polymorphisms.

In this study, p53 codon 72 and p21 codon 31 polymorphisms were evaluated in order to understand whether these two polymorphisms are associated with increased susceptibility for pterygium.

Patients and methods
A total of 128 pterygium patients (71 men and 57 women) were enrolled in the study with ages ranging from 35 to 90 years (mean 64.6 years). One hundred and three volunteers aged 55 years or more without pterygium were enrolled as the control group. There were 64 men and 39 women in the control group (age range from 50 to 83 years with an average of 64.2 years).

The genomic DNA was prepared from peripheral blood. For p53, the primer Pro 72 was designed for p53 codon 72 in proline form and Arg 72 for arginine form, according to the procedure described by Storey et al.1 For p21, the primer for codon 31 was designed from codon 1 start (5'-TCGACC GGCGGGGAGT-3') to codon 91 (5'-CTCT TCCAAACTCATCCC GG-3'), according to the procedure described by Li et al.1 The PCR products from the same individual were mixed together and 10 μl of this solution were loaded into 3% agarose gel containing ethidium bromide for electrophoresis.

Results
There were no significant differences between both groups in age and sex. The frequency of the genotype of p53 codon 72 and p21 codon 31 polymorphisms in the pterygium group and control group is shown in table 1. There were no significant differences between both groups. The frequency of the alleles for the p53 codon 72 and p21 codon 31 between pterygium and control groups was not statistically different (table 2).

Analysis of combination p53 codon 72 and p21 codon 31 polymorphisms, there was also no significant difference between both groups (table 3).

Comment
Weinstein et al suggest the cause of p53 mutation in pterygium may be ultraviolet radiation or be hereditary.1 Detorakis et al proposed a “two hit” model for DNA abnormalities in pterygium.1 The first hit could be either inherited or incurred by ultraviolet radiation, and the second hit could be caused either by solar light or by viral infection. Though the hereditary factor was proposed to have a role in pterygium formation, there were few studies to clarify this proposition. In this study, we try to investigate the hereditary factor of pterygium by single nucleotide polymorphisms (SNP) marker. Single nucleotide polymorphisms are the most abundant types of DNA sequence variation in the human genome, and the SNP marker has provided a new method for identification of complex gene associated diseases such as tumour.1 7

The p53 codon 72 and p21 codon 31 polymorphisms are two of the most important SNP markers for tumour susceptibility. However, there are no significant differences between the pterygium and control group in our study. We suggest the p53 codon 72 and p21 codon 31 polymorphisms maybe cannot

become useful genetic markers for pterygium susceptibility. This could be the basis of future surveys.

Pediatric ophthalmology and strabismus. 2nd ed

Pediatric ophthalmology is a large and developing subject and a new comprehensive, up to date text is much to be welcomed. In this revised edition of a major textbook, the editors and contributing authors have made great efforts to include many recent and important pieces of research. Despite this, there is a very practical flavour to most of the chapters; a nice touch is the inclusion of several practically useful tables (guidelines for planning strabismus surgery) and graphs of normal adnexal dimensions just within the covers.

Three new chapters have been added since the first edition; “Visual electrophysiology in children,” “Strabismus surgery,” and “Ocular disorders with systemic manifestations.” The first is a masterly and highly readable summary of the usefulness of electrophysiology in children and is a fitting tribute to one of the authors, Dr Tony Kriss, who sadly died soon after its completion. The chapter on strabismus surgery by Kenneth Wright contains elegant descriptions, beautifully illustrated, of a range of surgical techniques used in strabismus surgery. Finally, there is a unique account by Dr Maya Eibschitz-Tsimhoni, of the ocular manifestations of inherited disease. She includes a glossary of terms used to describe dysmorphic features, an alphabetical thesaurus of syndromes with prominent ocular features and many other alternative names and a clear description of the general and ocular findings in each, together with the genetic locus where known, or inheritance pattern. Generally, the neuro-ophthalmological and systemic or developmental problems are dealt with particularly well, but all of the chapters are comprehensive and well illustrated with clinical pictures and clear diagrams where appropriate.

I have rarely enjoyed reading a textbook as much as this one. My only complaint is of its bulk and the fact that apparently there is no CD version. This textbook is certainly useful enough for one to take it to clinics regularly but it is difficult to do this if attending outreach clinics, especially if carrying a laptop computer, an indirect ophthalmoscope, and a retinoscope as well. I would therefore warmly recommend this book to all ophthalmologists who see children but I would also beseech the publishers to think about a more portable medium for this potentially extremely useful text.

NOTICES

Low vision care

The latest issue of Community Eye Health (No 49) deals with the problems and management of low vision. For further information please contact: Journal of Community Eye Health, International Resource Centre, International Centre for Eye Health, Department of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT, UK (tel: +44 (0)20 7612 7964; email: Anita.Shah@lshtm.ac.uk; online edition: www.jech.co.uk). Annual subscription (4 issues) UK £28/US$45. Free to developing country applicants.

Elimination of avoidable blindness

The 56th World Health Assembly (WHA) considered the report on the elimination of avoidable blindness (doc A56/26) and urged Member States to: (1) Commit themselves to supporting the Global Initiative for the Elimination of Avoidable Blindness by setting up a national Vision 2020 plan by 2005; (2) Establish a national coordinating committee for Vision 2020, or a national blindness prevention committee to help implement the plan; (3) Implement the plan by 2007; (4) Include effective monitoring and evaluation of the plan with the aim of showing a reduction in the magnitude of avoidable blindness by 2010; (5) To support the mobilisation of resources for eliminating avoidable blindness. The WHA also urged the Director-General to maintain and strengthen WHO’s collaboration with Member States and the partners of the Global Initiative for the Elimination of Avoidable Blindness as well as aid in the coordination and support of national capability.

XVIth Meeting of the International Neuro-Ophthalmology Society

4th International Congress on Autoimmunity

The 4th International Congress on Autoimmunity will take place 18-21 November 2004 in Budapest, Hungary. The deadline for the receipt of abstracts is 20 June 2004. Further details: Kenes International Global Congress Organisers and Association Management Services, 17 Rue du Cendrier, PO Box 1726, CH-1211 Geneva 1, Switzerland (tel: +41 22 908 0488; fax: +41 22 732 2850; email: autoim04@kenes.com; website: www.kenes.com/autoim04).

Optometry giving sight launches new website

Optometry Giving Sight (OGS) is delighted to announce the launch of its official website www.givingsight.org which will go live on Friday 21 May 2004. Further to VISION 2020’s recent announcement that HRH The Countess of Wessex will be showing her support for the ground-breaking campaign OGS at a luncheon she will be attending at the Mansion House on Monday 17 May, the launch of the website is another step forward in the progress of this exciting new project.

OGS is a unique collaboration of the International Agency for the Prevention of Blindness (IAPB), World Optometry Foundation (WOF) and the International Centre for Eyecare Education (ICEE). The purpose of the OGS project is to generate new income primarily from the Optometrists, Optical Dispensers, Optometric Practices, Opticians and optical outlets throughout the world, for the purposes of VISION 2020: The Right to Sight, including the delivery of eye and vision care; the development of human resources; and the improvement of infrastructure needed to improve eye care services around the world. Attached is the web launch press release, OGS poster and a photograph with caption. For further information, please contact: Isabel Gandier (tel: +44 7879 824 400; e-mail: igander@v2020.org; website: www.givingsight.org) and for further information on ‘VISION 2020: The Right to Sight’ please visit www.v2020.org.

CORRECTION

In the letter by Shortt et al (Br J Ophthalmol 2003;87:1302), the image presented in fig 3 was the incorrect figure. The correct figure is shown below. The journal apologises for the error.

Figure 3 Postoperative MRA. Normal blood flow is present in both ophthalmic arteries (arrows).
