Orbital varices and orbital wall defects

Orbital varices are a vascular hamartoma typified by a plexus of low pressure, low flow, thin walled and distensible vessels that intermingle with the normal orbital vessels. If freely communicating with the orbital circulation, engorgement of varices can occur by increasing venous pressure through the Valsalva manoeuvre, bending posture, coughing or straining and these, in turn, lead to the clinical characteristics of variable proptosis, intermittent pain, and orbital haemorrhage.

Observation is usually warranted for small lesions, but surgical intervention may be necessary in advanced cases: indications for surgical intervention include non-resolving episodes of thrombosis, severe disfiguring proptosis or displacement of the globe, and optic nerve compression. Surgery can be extremely difficult, as varices are very friable and intimately intermixed with normal orbital structures; there is also a significant risk of visual loss as a result of haemorrhage or optic nerve damage, the latter being generally caused by vascular compromise. The association of orbital venous anomalies with orbital wall defects provides a further source of surgical difficulty because of the close proximity of intracranial structures and the continuity with extraorbital or intracranial venous anomalies.

Case series

The orbital database, at Moorfields Eye Hospital, was used to identify patients with a clinical diagnosis of low pressure orbital varices and their orbital imaging (computed tomography and/or magnetic resonance image) was reviewed. Images were examined for evidence of orbital expansion, osseous defects of the orbit, nose or sinuses, and anomalies of the frontal lobes. Patients who had orbital or intracranial surgery before the date of imaging were excluded from the investigation.

The clinical diagnosis of orbital varices was identified in 310 patients, and imaging was available for 223 patients (72%). Six patients with previous orbital or intracranial surgery were excluded and nine cases (4%) had associated anomalies of the neighbouring orbital walls (table 1).

Four cases (patients 1–4) were associated with “pitting” of the orbital wall secondary to orbital varices (fig 1A). Another three cases (patients 6–8) were associated with enlarged superior orbital fissure and two cases (patients 5 and 9) with multiple orbital roof “defects” (fig 1B). Orbital varices were present up to the dural space in two cases (patients 4 and 5), and involved the frontal lobe parenchyma in one case (patient 6; fig 1C, D).

Figure 1 (A) (Patient 1) Extensive left orbital varices (white arrows) causing orbital expansion, globe displacement, and “pitting” of the orbital roof and lamina papyracea (black arrows). (B) (Patient 5) Bilateral orbital varices associated with multiple defects, rather than pitting, of the orbital walls. (C) (Patient 6) Right orbital varices, with phleboliths, extending through the orbital apex into the middle cranial fossa (white arrows) and (D) associated with intracranial bone “pitting” and “defects” (black arrows). (E) Coronal and (F) axial CT scans of patient 2 with superonasal varices (white arrows) of right orbit in 1981. (G–J) Repeat coronal and axial CT scans in 2001 show significant enlargement of the bone defect with complete loss of mineralisation, and expansion of the frontal lobe meninges into the orbital wall defect (black arrow).
neighbouring orbital circulation enhancement, in communication with the lateral mass, with some patchy contrast in brain, bone, and varix. The typical findings provide an excellent natural contrast between which occur from thrombus formation, delineate varices and diagnostic phleboliths, Fine cut (3 mm) orbital CT scans easily

Comment

Fine cut (3 mm) orbital CT scans easily delineate varices and diagnostic phleboliths, which occur from thrombus formation, and provide an excellent natural contrast between brain, bone, and varix. The typical findings for varices include an ill defined multiloculated mass, with some patchy contrast enhancement, in communication with the neighbouring orbital circulation; diffuse expansion of the orbital walls is well recognized in some cases, especially in childhood lesions. Several factors may have biased the study population: many are symptomatic patients, having been referred from other ophthalmic units in consideration for surgical intervention. The apparent incidence of orbital wall defects (4%) in our series may, therefore, be a slight overestimate. In a minority of patients, orbital varices may be associated with orbital wall defects, and such defects may, eventually, lead to an encaphalocoele formation. Clinicians should be aware of these, apparently unreported, associations before embarking on surgical intervention for orbital varices.

Exenteration of invasive conjunctival squamous cell carcinoma

Ocular surface squamous neoplasia (OSSN) includes conjunctival intraepithelial neoplasia with dysplasia, carcinoma in situ and conjunctival squamous cell carcinoma (SCC). Beside ultraviolet B irradiation identified as a risk factor, OSSN is associated with human papillomavirus type 16 and 18 (HPV-16, HPV-18).1 The exact role and possible prognostic value of p53 overexpression is unclear and little is known about its expression during the development of conjunctival SCC.

Patient 1

A 75 year old man was referred with a 10 year history of a conjunctival mass of the left eye with visual acuity of hand movement. Previous biopsies had revealed conjunctival dysplasia. On examination, the tumour of the ocular and tarsal conjunctiva of the lower lid covered the entire corneal surface (fig 1A).

Case reports

Patient 1

A 75 year old man was referred with a 10 year history of a conjunctival mass of the left eye with visual acuity of hand movement. Previous biopsies had revealed conjunctival dysplasia. On examination, the tumour of the ocular and tarsal conjunctiva of the lower lid covered the entire corneal surface (fig 1A).

Patient 2

A 90 year old patient presented with a 2 year history of an extensive conjunctival papillomatous tumour of the left eye covering three quarters of the cornea with visual acuity of light perception. A full thickness biopsy was performed.

Both patients underwent orbital exenteration including removal of the eyelids. Histopathologically the focal invasive, completely removed tumour of patient 1 grew in a papillomatous manner. The tumour cells of the conjunctival neoplasm showed strongly enlarged nuclei with prominent nucleoli, and formed cohesive units with intercellular bridges (fig 1B).

The exophytic tumour of patient 2 was predominantly intraepithelial with foci of subepithelial invasion. Focal tumour anaplasia was observed in the otherwise moderately differentiated tumour with squamous cell differentiation.

Immunostaining of both specimens revealed strong p53 (monoclonal mouse anti-human p53-protein DO-7, Dako) overexpression (>26% of epithelial cells) and low expression of p21 (<6% of epithelial cells) of the invasive region of the tumour indicating an inactivating p53 mutation (fig 1C). While in patient 1 expression for p53 was found in all epithelial layers, in patient 2 it was expressed suprabasally. In contrast, both p53 and p21 showed moderate reactivity in the dysplastic region up to the middle layer of the tumour (fig 1D). In the apical layer epithelial cells were occasionally p21 positive.

Immunostaining for HPV (HPV screening antibody, Virofem Diagnostica, Germany) was positive in patient 1.

Comment

The high recurrence rate of OSSN of 9–64% after resection seems to depend on the histopathological grade and status of surgical margins.1 HPV-16 and HPV-18 are considered
to be possible cofactors involved in initiation and early progression of OSSN. Though both of the presented tumours were clinically papillomatous, immunostaining for HPV was positive only in patient 1. The tumour suppressor gene p53 has been found to be inactivated in over 50% of human cancers. In OSSN, overexpression of p53 has been previously reported in some SCC of conjunctiva. In the SCC of our patients, p53 overexpression indicating inactivating p53 mutations were observed only in the invasive part of the tumour, but not in the carcinoma in situ. While Dushku and coworkers assumed that p53 mutations could be an early event in tumour development consistent with ultraviolet radiation, our findings clearly indicate that mutations of p53 are a late event that occur with disease progression, as observed with other solid tumours. Karciglu and associates found a correlation between p53 overexpression and unfavourable clinical course. In contrast, Aoki and colleagues found no expression for p53 in SCC but positive staining in dysplasia.

Our results of two exenterated advanced stages of SCC emphasise the necessity to remove dysplastic OSSN completely to prevent progression to invasive carcinomas. Identification of inactivating p53 mutations may indicate an increased risk for invasiveness. Therefore immunohistochemical analysis of biopsy specimen may help in the management of these tumours.

Figure 1 Patient 1. (A) Extensive papillomatous tumour, subtotally covering the corneal surface of the left eye. Nodular thickening of the lower eyelid indicates eyelid involvement. (B) Histological appearance. Papillomatous pattern of the large epithelial lesion with focal invasion above the cornea. Subepithelially, inflammatory cells and some dilated vessels (haematoxylin and eosin, original magnification, ×2.5). (C) p53, showing strong diffuse reactivity in invasive region indicating an inactivating p53 mutation (original magnification, ×10). (D) p53, showing moderate expression predominantly in the suprabasal layers in dysplastic conjunctiva of the same specimen (original magnification, ×10).

Familial pseudotumoral sclerochoroidal calcification associated with chondrocalcinosis

Sclerochoroidal calcification is the deposition of calcium at the level of the sclera and choroid. Two entities have been described: metastatic calcifications resulting from deposition of calcium in normal tissues caused by phosphocalcic metabolism abnormality such as primary and secondary hyperparathyroidism, pseudohyperparathyroidism, hypervitaminosis D, vitamin D intoxication, hypophosphataemia, sarcoidosis, Barter syndrome, and Gietelman syndrome; and dystrophic calcifications caused by secondary deposition of calcium in abnormal tissues despite normal serum levels of calcium and phosphate.

Sclerochoroidal calcifications can also be idiopathic. We describe the first case of hereditary form of sclerochoroidal calcifications associated with familial articular chondrocalcinosis.

Case report

A 69 year old man was admitted to the department of ophthalmology in November 1999 with gradual deterioration of vision in both eyes. He had a medical history of familial articular chondrocalcinosis. His father, brother, and son were treated for the same disease.

On examination, best corrected visual acuity was 20/120 in the right eye and finger counting in the left eye. Slit lamp examination and ocular tension were normal. The funduscopy revealed multiple bilateral pseudotumoral white choroidal masses in both eyes (fig 1). Ultrasound examination of the eyes confirmed the calcific nature of the lesions.

On fluorescein angiography in March 1979 the pseudotumoral lesions were smaller and did not involve the macular area in left eye (fig 1).

He had an extensive metabolic evaluation which was normal. The systemic diagnosis was familial articular chondrocalcinosis. We decided to examine the whole family to search for ophthalmic abnormalities linked with familial chondrocalcinosis.

The 74 year old brother and the 40 year old son also suffered from chronic articular chondrocalcinosis. Their best visual acuity was 20/20 in both eyes.
Figure 1: Fluorescein angiography of the 69 year old patient in 1979 (left) and 2000 (right) showing evolution of the sclerochoroidal calcifications with time.

The brother’s funduscopy revealed multiple bilateral, extrafoveal pseudotumoral white choroidal masses (fig 2, top). The son’s funduscopy revealed plaque-like and only slightly elevated lesions seen in the midperiphery (fig 2, bottom). Ultrasonograms confirmed the calcific nature of these lesions.

Comment

In 1997, Shields et al reported a case of sclerochoroidal calcifications in a normocalcaemic patient who had chondrocalcinosis. We first describe a familial case of sclerochoroidal calcifications associated with calcium pyrophosphate dihydrate (CPPD). In this family, autosomal dominant inheritance is highly likely because there are affected individuals in each generation, there is male to male transmission, and every affected member has an affected parent.

Inheritance in sclerochoroidal calcifications has never been described; however, hereditary forms of chondrocalcinosis have already been described.

In our report, a patient had a 24 year follow up showing a progressive involvement of the macular area, suggesting a growth of the calcifications. Two types of calcifications have been described previously, the plaque-like and the pseudotumoral type.

To our knowledge, it has never been determined if the plaque-like lesions evolve into tumour-like lesions. In 1992, Schachat and associates reported 10 cases with follow up ranging from 7 months to 10 years, for whom no change in the lesion was seen. This is the first observation with 24 years of follow up suggesting a possible evolution of plaque-like lesions to pseudotumoral lesions.

We suggest that every patient affected by familial chondrocalcinosis should have an ophthalmic examination to detect sclerochoroidal calcification. These lesions seem to be evolving in time with possible involvement of the macula. Choroidal neovascularisation is also a vision threatening complication of sclerochoroidal calcifications. Our case suggests the need to perform ophthalmological examination in patients and family members of patients affected by chondrocalcinosis.

Whole body PET/CT imaging for detection of metastatic choroidal melanoma

Metastatic choroidal melanoma typically presents in the liver. Therefore, liver enzyme assays are the most common haematological evaluation performed after treatment. In 1985, The Collaborative Ocular Melanoma Study required periodic medical evaluations including a physical examination, liver functions studies, a complete blood count, and a chest x-ray. If liver enzymes exceeded 1.5 times normal, computed tomography (CT) of the abdomen was required. If low attenuation hepatic nodules suggested metastatic disease, fine needle aspiration biopsy of the liver tumours provided cyto-pathological confirmation.

Positron emission tomography (PET) is a molecular imaging technique that uses radiolabelled molecules to image metabolic activity in vivo. When whole body PET was combined with computed radiographic tomography (CT), PET/CT put anatomy and function on the same page making practical a new era of physiological imaging.

This study examines the ability of positron emission tomography combined with computed tomography (PET/CT) to allow for detection of previously occult metastatic melanoma.

Case report

A 77 year old woman presented with a 15.4×15 mm width and 13.2 mm high collar button shaped choroidal melanoma with a large secondary retinal detachment in her right eye. Her preoperative medical evaluation
Two years later a follow up medical evaluation revealed elevated liver function studies (table 1) and a chest x ray showed a pleural effusion. CT of the abdomen with contrast revealed multiple low attenuation hepatic foci consistent with metastatic melanoma.

A PET/CT was requested. Fifty minutes after intravenous administration of 15.2 mCi of fluordeoxyglucose, whole body PET/CT imaging revealed enlarged para-aortic lymph nodes and a subcutaneous nodule in the abdominal wall (fig 1). The CT portion of the PET/CT also revealed two 3 mm nodules in the right upper lobe. PET imaging was able to reveal multiple bony metastases that were not seen on the CT portion (fig 1). Both CT and PET showed a large liver metastasis.

Comment

In this case, whole body PET/CT was found to be capable of uncovering metastases not seen with abdominal CT alone. This led us away from considering regional perfusion of the liver, hepatic resection, and towards systemic treatment. Therefore, when PET/CT identifies extrhepatic involvement, it can have a significant impact on the management of patients with metastatic choroidal melanoma.

PET/CT could also be used for initial staging. Early detection of occult metastases

Enlarged

High bilirubin, AST, ALT, alkaline phosphatase, GGT

Enlarged. 2 areas of low attenuation in the anterior aspect of the right lobe

Low attenuation lesion ≥20 cm in greatest diameter in the right lobe with calcification seen posteriorly. Numerous low attenuation lesions throughout both lobes of the liver

Enlarged. Large hypermetabolic focus in the right lobe with mass effect. Numerous hypermetabolic foci throughout remainder of liver

Kidney

8 mm cyst midpole and 2 cm cyst upper pole of left kidney

Large right renal cyst. Additional smaller cysts

Photopenic defect due to large right renal cyst

Bone

No lesions noted

No lesions noted

Hypermethylated foci in the right skull base, left scapula, left humerus, sternum, multiple bilateral ribs, thoracic and lumbar spine, pelvis, and bilateral femurs

Two years later a follow up medical evaluation revealed elevated liver function studies (table 1) and a chest x ray showed a pleural effusion. CT of the abdomen with contrast revealed multiple low attenuation hepatic foci consistent with metastatic melanoma.

A PET/CT was requested. Fifty minutes after intravenous administration of 15.2 mCi of fluordeoxyglucose, whole body PET/CT imaging revealed enlarged para-aortic lymph nodes and a subcutaneous nodule in the abdominal wall (fig 1). The CT portion of the PET/CT also revealed two 3 mm nodules in the upper lobe of the right lung (too small to be visualised by PET imaging). PET imaging was able to reveal multiple bony metastases that were not seen on the CT portion (fig 1). Both CT and PET showed a large liver metastasis, but CT was better at defining tumour size. Since it is a physiological assay, PET also demonstrated the metabolic activity of the metastatic tumours (fig 1).

Comment

In this case, whole body PET/CT was found to be capable of uncovering metastases not seen with abdominal CT alone. This led us away from considering regional perfusion of the liver, hepatic resection, and towards systemic treatment. Therefore, when PET/CT identifies extrhepatic involvement, it can have a significant impact on the management of patients with metastatic choroidal melanoma.

PET/CT could also be used for initial staging. Early detection of occult metastases

Figure 1 On the left, the CT demonstrates the anatomy; on the right the PET shows areas of hypermetabolism (glucose uptake); in the middle the two images are fused. PET/CT revealed enlarged para-aortic lymph nodes and a subcutaneous nodule in the anterior abdominal wall. The PET imaging portion of the PET/CT was able to reveal multiple bony metastases that were not seen on the CT portion of the examination. Both CT and PET showed a large liver metastasis.
offers the potential to avoid ineffective and expensive enucleations, radioactive plaques, proton irradiation, eye wall resections, or laser treatment. Local therapies would be abandoned in favour of systemic treatments.

Another issue related to PET/CT is cost. Up to five times more than CT of the abdomen, PET findings). Since PET/CT revealed hepatic foci in this case, it changed our clinical approach. There is little doubt about the improved ability of PET/CT to detect lesions; the real issue is cost and if the results will change outcomes.

This study goes one step further than CT, MRI, or PET alone. By combining whole body PET and CT, this examination joins anatomy and function in one examination (fig 1). The relative efficacy of PET/CT to locate metastases should be evaluated within the framework of a prospective study.

Trans-Tenon’s retrobulbar triamcinolone infusion for small choroidal neovascularisation

Intraocular and sub-Tenon’s corticosteroids are intravenously evaluated for the treatment of choroidal neovascularisation (CNV). We report the efficacy of triamcinolone acetone administered as a trans-Tenon’s retrobulbar infusion (triamcinolone infusion) in reducing inflammation in uveitic eyes. Here we evaluated the same treatment in eyes with small subfoveal CNV.

Case reports

Tiamcinolone infusion was performed in 22 eyes of 22 patients with subfoveal CNV of greatest diameter less than or equal to 1 disc diameter (DD). The diagnoses were age-related macular degeneration (AMD) in 14 eyes, idiopathic CNV in four eyes, polypoidal choroidal vasculopathy (PCV) in three eyes, and punctate inner choroidopathy (PIC) in one eye. One AMD eye had undergone ablative argon laser photocoagulation for CNV previously, but no other eyes had received previous treatment. The median post-triamcinolone infusion follow up was 7.5 months (range 4–27 months). Pretreatment fluorescein angiography (FA) revealed predominantly classic CNV in 12 eyes and predominantly occult CNV in 10 eyes. Records were reviewed retrospectively and did not require institutional review board approval. Informed consent was obtained before each procedure.

Trans-Tenon’s retrobulbar triamcinolone infusion for small choroidal neovascularisation

Trans-Tenon’s retrobulbar triamcinolone infusion for small choroidal neovascularisation

Trans-Tenon’s retrobulbar triamcinolone infusion for small choroidal neovascularisation

Trans-Tenon’s retrobulbar triamcinolone infusion for small choroidal neovascularisation

Figure 1 Colour fundus photographs and fluorescein angiography late images of an eye in a 65 year old patient with age related macular degeneration and small subfoveal choroidal neovascularisation before (A, B; best corrected visual acuity 0.3) and 3 months after triamcinolone infusion (C, D; best corrected visual acuity 0.7).
unchanged in 10 eyes (71%), and worsened by >0.2 logMAR in three eyes (21%). In these AMD eyes, the median decimal VA was 0.30 before treatment (range 0.08–1.0) and 0.20 at 3 months after treatment (range 0.05–0.7). Complications such as intraocular pressure elevation, infection, or cataract progression were not noted in any eyes.

**Comment**
This interventional case series shows that trans-Tenon’s retrobulbar infusion of triamcinolone acetonide resulted in lesion fibrosis in the majority of eyes with small CNV, efficacy being best for idiopathic CNV or CNV related to PIF. The mechanism of action of triamcinolone acetonide in inhibiting CNV growth probably involves several pathways. The effect of corticosteroids in inhibiting angiogenesis has specifically been shown to inhibit basic fibroblast growth factor induced migration and tube formation of choroidal microvascular endothelial cells. Furthermore, triamcinolone acetonide inhibits choroidal neovascularisation induced by laser trauma in a rat model. Finally, triamcinolone acetonide may decrease vascular permeability, thereby decreasing influx of serum proteins that may contribute to an angiogenic micro-environment. Longer follow up and greater numbers of cases in a randomised clinical trial are needed to confirm these results.

**Retinoblastoma in children conceived by in vitro fertilisation**

As the number of infants born through in vitro fertilisation (IVF) grows, there is increased interest regarding the long term effects of IVF and other assisted reproduction techniques on such offspring. Recent reports have noted cancer in children born after IVF or fertility drug use (table 1).

In 2001, retinoblastoma was reported to occur in a child born through IVF in Israel. Since then, an additional report documented four cases from the Netherlands. Here we add a sixth case and the first from the United States. Of these children four had unilateral retinoblastoma and two bilateral disease (table 2).

During 2002, a 16 month old child was referred to The New York Eye Cancer Center with no known family history of eye disease. She had a blind painful right eye with neovascular glaucoma. Intraocular pressures were 35 mm Hg in the right eye, and 14 in the left. Examination of the anterior chamber of the right eye revealed cells on the corneal endothelium and iris neovascularisation. While ophthalmoscopic examination of the right eye was not possible because of opaque media, ultrasonography revealed a densely calcified mass in the posterior pole (fig 1). Computed radiographic tomography demonstrated tumour calcification with no evidence of extrascleral or optic nerve extension. Post-enucleation histopathology confirmed the diagnosis of retinoblastoma. The parents did not approve genetic studies of the child.

Further history revealed that this child was born through IVF with a donor egg and the father’s sperm. In order to carry the child, the postmenopausal mother received oestrogen and progesterone before and during gestation.

**Comment**
Several theories of IVF related carcinogenesis exist. Prenatal exposure to fertility drugs may initiate cancer in the embryo or parental germ cells. However, an evidence based association between IVF treatments and cancer development (in the women taking the drugs) has not been established.

Another possible mechanism has been associated with the culture medium used in the IVF test tube. Experiments on mice suggest that subtle changes in the ingredients of the culture media may alter the activity of imprinting genes. Like fertility drugs, it remains to be seen whether altered gene imprinting can lead to cancers such as retinoblastoma.

A third possible mechanism of carcinogenesis includes inheritance of genetic defects from gametes and embryo trauma performed during routine intracytoplasmic sperm injection (ICSI) type IVF.

The most likely explanation for an increased risk of secondary carcinogenesis is that the population of patients seeking IVF is dissimilar to the general population. Patients seeking IVF are older or have medical problems that interfere with fertility. This poses a problem with any study other than a randomised prospective trial that compares babies from untreated infertility patients who become pregnant versus babies from infertile patients who become pregnant using IVF. To date all studies published are observations of clusters of disease with the suggestion that there is a cause and effect relation.

www.bjophthalmol.com

Retinoblastoma is the most common intraocular cancer of childhood and affects approximately 300 children each year in the United States. Retinoblastoma is a manifestation of a de novo deletion or mutation of the q14 band of chromosome 13, occurring as a "second hit" during embryogenesis or the result of two hit deletions in retinal cells. In that it could be the result of chromosomal breakage and deletions in IVF born children, surveillance of retinoblastoma incidence in children born through IVF is warranted.

With the advent of assisted reproductive technology (ART) in 1977, American couples have increasingly turned to such treatments to overcome fertility problems. Nationwide, 99,629 procedures were performed in 2000 by ART. In that year, fertility treatments in which the egg and sperm are handled in the laboratory resulted in 25,228 live births and 629 left eye, with 200–240 mW, 0.4 second duration, was performed by a paediatric ophthalmologist. On the following day, severe hyphaema was observed bilaterally but there was no evidence of choroidal detachment by B-mode ultrasound sonography. Topical atropine and corticosteroid were started and she was

Angle closure glaucoma after laser photocoagulation for retinopathy of prematurity

Infantile angle closure glaucoma (AGC) is a rare consequence of retinopathy of prematurity (ROP) and usually occurs a few years after laser treatment for ROP. A Medline search for AGC following laser photocoagulation extracted only one case. In the case, AGC occurred in 2 weeks after laser photocoagulation and although occurrence of iris bombe in both eyes was described, the mechanism for the AGC was not fully clarified.

We present a case of bilateral AGC that occurred within a several weeks after the laser photocoagulation for ROP. We shall discuss the importance of ultrasound biomicroscopy (UBM) in the diagnosis.

Case report

A baby girl, born at 25 weeks gestation weighing 796 g, was diagnosed with stage 2 plus, zone 2 ROP bilaterally at 33 weeks. Diode laser photocoagulation, 986 applications right eye and 629 left eye, with 200–240 mW, 0.4 second duration, was performed by a paediatric ophthalmologist. On the following day, severe hyphaema was observed bilaterally but there was no evidence of choroidal detachment by B-mode ultrasound sonography. Topical atropine and corticosteroid were started and she was...
endothelium. As a result, the anterior capsule right iris surface was adherent to the corneal strated iris bombe bilaterally, and the entire (fig 1). observed but rubeosis iridis was not observed branes and iridohyaloid vessels were 17 mm Hg left eye. Persistent pupillary mem- cult bilaterally. The IOP under the general corneal oedema made the funduscopy diffi- bilaterally, especially in the right eye. The oedema and shallow anterior chamber depth Slit lamp examination showed corneal diameter was increased to 11 mm bilaterally. [Image 70x465 to 218x743] UBMs of anterior segments demonstrated iris bombe bilaterally, and the entire right iris surface was adherent to the corneal endothelium. As a result, the anterior capsule followed up conservatively. During the follow up period, total posterior synchiae was formed in the both eyes and the anterior chamber became shallow. At 39 weeks, the corneal diameter had increased, and the anterior chamber was extremely shallow bilaterally. The intraocular pressure (IOP) in the right eye was elevated extremely shallow bilaterally. The intraocular pressure (IOP) in the right eye was elevated caused the hyphaema. We are not aware of another possibility is an acciden- hyphaema was derived from vitreous haemorrhage. Another possibility is an accidental phacoemulsification of persistent pupillary membranes and/or iridocorneal vessels caused the hyphaema. We are not aware of such morphological changes after phacoemulsification for ROP. ACG that occurs immediately after retinal phacoemulsification in ROP patients is rare, but it is still an important complication. In ROP patients, the lens and its ligament are weak, and therefore not only ACG but also lens displacement occurred. It is important that we be aware of the possible development of ACG following retinal phacoemulsification for ROP.

Sequential treatment of central retinal vein occlusion with intravitreal tissue plasminogen activator and intravitreal triamcinolone

Treatment for central retinal vein occlusion (CRVO) remains disappointing despite recently proposed intraocular surgical techniques. We previously introduced the use of intravitreal tissue plasminogen activator (TPA) for acute central retinal vein occlusion in 1999. Numerous investigators have confirmed its safety and suggested that it may have a beneficial role in the treatment of acute central retinal vein occlusion. Although some studies in rabbits suggest the rabbit retina is not permeable to TPA, [Image 391x120 to 540x500] Figure 1 (A) Fundus photograph shows an acute CRVO with dilated retinal veins, retinal haemorrhages, and retinal oedema. (B) Fundus appearance 1 month after intravitreal injection of tissue plasminogen activator. (C) Photograph of the same eye 5 months later.
being advised of the risks and the benefits, the patient then underwent injection of intravitreal triamcinolone (4 mg).

Six weeks after the intravitreal triamcinolone, the FA returned to normal and OCT showed decreased foveal thickness from 331 μm to 291 μm. The patient reported a significant improvement in vision with decreased metamorphopsia. Vision was 20/25 with no late leakage on the fluorescein angiogram (fig 2B).

Comment
To our knowledge, this represents the first published case of CRVO treated sequentially with intravitreal TPA for the acute phase and intravitreal triamcinolone for the chronic phase. TPA is a drug that must be used early in the course of thrombus formation to be effective. We do not recommend its use for patients with chronic symptoms. Intravitreal steroids appear to decrease the blood-retinal barrier breakdown and macular oedema, but recurrent oedema may occur since the steroids do not appear to affect the thrombus itself.

Case report
A 59 year old obese, hypertensive flight instructor presented with a sudden decrease in vision for 7 days in his right eye. Vision was 20/400 right eye and 20/20 left eye. The patient was diagnosed with an acute CRVO in his right eye (fig 1A). The left eye was normal. After being advised of the risks and benefits, the patient elected to undergo intravitreal injection of TPA (75 μg). Thirteen days later, the patient noted marked improvement in vision with 20/60 vision. Thirty four days after the injection, the patient’s vision was 20/30 (fig 1B).

Six months after intravitreal TPA injection, vision remained 20/30, but the patient still complained of metamorphopsia and blurry vision despite resolution of other findings of CRVO (fig 1C). Fluorescein angiogram (FA) revealed persistent macular oedema (fig 2A). Optical coherence tomography (OCT) showed the foveal thickness to be 331 μm with mild intraretinal oedema. After

Severe post-laser suprachoroidal haemorrhaging in a diabetic patient receiving anticoagulants
Although the aetiology is not well understood, expulsive suprachoroidal haemorrhaging (ESH) is the most severe complication associated with intraocular surgery. Anticoagulants are considered a risk factor for spontaneous suprachoroidal haemorrhaging in cases with high myopia, age related macular degeneration, and diabetic retinopathy.11 However, ESH post photoocoagulation is extremely rare regardless of anticoagulant therapy. We have experienced a severe case of post-laser ESH correlated with anticoagulant therapy, which resulted in irreversible visual disturbance.

Case report
A 70 year old woman was diagnosed with pre-proliferative diabetic retinopathy based on fluorescein angiographic examinations. Two months before diagnosis, she had right eye cataract surgery. During the past 6 years, the patient received warfarin (4 mg/day) and aspirin (81 mg/day) because of atrial fibrillation after myocardial infarction. Laser photocoagulation was performed in her right eye with a Nidek MC-7000, yellow-green laser. Operating conditions were 200–280 burns per session with a spot size 200 μm, exposure 0.2 seconds, power 100–120 mW using a Quadrifocal contact lens (Volk, Tokyo, Japan). Treatment was separated into three partitions with a minimum 2 week interval between sessions. Three days after final photocoagulation, the patient had a sudden visual loss to hand movements. In slit lamp examinations, the retina seemed to be detached. Treatment was separated into three partitions with a minimum 2 week interval between sessions. Three days after final photocoagulation, the patient had a sudden visual loss to hand movements. In slit lamp examinations, the retina seemed to be detached. Treatment was separated into three partitions with a minimum 2 week interval between sessions. Three days after final photocoagulation, the patient had a sudden visual loss to hand movements. appropriate for post-cardiac infarction). Presumably, choroidal microbleeding initiated by photoocoagulation persisted because of an overly suppressed coagulation system; blood pooled in the choroidal space, which assumed an ESH. To our knowledge there is only one other similar case reported by Khairallah et al that showed post-laser choroidal haematoma in a diabetic patient treated with anticoagulant. Even though ESH incidence is low, extreme caution must be exercised when performing laser therapy in patients using anticoagulants, because of potentially serious outcomes. An age of 65 years or more, history of stroke, history of gastrointestinal bleeding, a serious morbid condition (recent myocardial infarction, renal insufficiency, or severe anaemia), and atrial fibrillation are five high risk factors for major bleeding in outpatients treated with warfarin." If possible, preoperative coagulation system examinations are recommended for high risk patients receiving anticoagulant treatments.

Figure 1 A fundus photograph of the patient after laser photoocoagulation. A severe choroidal detachment associated with secondary retinal detachment was found.

Figure 2 The findings of B-mode ultrasound examination. A massive haemorrhage in the choroids is present.

Authors’ reply
We appreciate the interest and many comments we have received regarding our recent article. In reply to the comments by Dr Vedanam, we acknowledge the paucity of experimental data to prove that accurate placement of corticosteroids into the sub-Tenon’s space provides good drug penetration into the eye. However, the studies to the contrary cited by Vedanam have all used needles to make such “accurate placement,” including the study by Jennings et al, which utilised the technique described by Tessler. Use of needles represents not only a potential hazard to the eye in terms of accidental globe penetration, but also makes it much more difficult to place any sub-Tenon’s injection under the posterior Tenon’s capsule near the macula and/or around the optic nerve. It has been shown that many in the literature for the sub-Tenon’s space merely end up somewhere in the orbit outside of Tenon’s capsule. We believe that our method using a 23 gauge blunt, curved, long cannula (the one we used was No HS-2764 by Handaya Co, Ltd, Tokyo, Japan) assures accurate placement into the target space, thereby increasing therapeutic efficacy and obviating the need for globe invasive procedures such as intravitreal injection of corticosteroids, corticosteroid intravitreal implants, and/or therapeutic vitrectomy.

However, we are in agreement with Vedanam, in that ultimately corticosteroids placed outside of the eye may be the search for the efficacy that may be obtained by corticosteroid placed inside the eye. Yet we have found such a high efficacy rate for the trans Tenon’s retrobulbar infusion of triamcinolone in uveitis that we can conceive of no reason why this treatment should not be tried before surgical injections that carry risks of severe complications are considered. For example, as also pointed out by Vedanam, the risks of intravitreal corticosteroid injections even include development of a rare form of mycobacterial endophthalmitis. Therefore, the risk to the eye of intravitreal procedures especially when involving corticosteroid administration, cannot be taken lightly. Furthermore, we believe that the reason why sub-Tenon’s injections of corticosteroids have not become popular among retina specialists who for example treat diabetic macular oedema, is more likely related to the lower efficacy rate when using needles as opposed to the technique using an infusion cannula that we advocate. Lastly, obtaining the infusion cannula seems like a small inconvenience (and an even smaller cost) to the physician compared to the risk of doing intravitreal injections of corticosteroids as a treatment of first choice as advocated by Vedanam. We strongly encourage all uveitis and retina specialists who have up until now been disappointed with the efficacy of their sub-Tenon’s corticosteroid injections, to make the effort to obtain an appropriate cannula and revise their technique before jumping to intravitreal procedures.

In reply to the first comment by Dr Mehta, we acknowledge the current WHO guidelines, revised for 2003, that include recommendations for extrapolummary tuberculosis. However, we would also like to amend Mehta’s comment, in that the WHO admits conditions for extrapulmonary tuberculosis.

www.bjophthalmol.com
regimens with reported efficacy including a 6 month regimen of rifampicin (with streptomycin also given in the initial phase only) for presumed tuberculous uveitis. Furthermore, the WHO recommendations are for active extraocular tuberculosis that has been diagnosed by specimen examination or strong clinical evidence, and give no recommendations for latent infection. As we have previously reported in a series on intraocular tuberculosis, systemic examination failed to identify a focus of active tuberculosis in the majority of our patients, and we have come to suspect that the uveitis we observed may be an immune response to latent tuberculosis antigen sequestered elsewhere. Therefore, the patients we described were given a diagnosis of ‘presumed intraocular tuberculosis,’ that is with uveitis presumed to be related to the Mycobacterium tuberculosis organism. Furthermore, we would like to clarify that in the cases of presumed ocular tuberculosis that received trans-Tenon’s retrobulbar triamcinolone infusion, this treatment was judged to be effective in two of three eyes. Regardless, since the focus of active or latent tuberculosis was never identified in our patients, a two drug regimen of isoniazid and rifampicin was used as a therapeutic trial for anti-tuberculosis therapy. A similar therapeutic protocol for ocular tuberculosis, albeit with isoniazid alone, has been previously advocated in Japan by Ishihara and Ohno. With regard to the second comment, among the 16 patients who were receiving some form of systemic immunosuppressive therapy, we did not notice any difference in outcome when compared to patients who were not on immunosuppressive therapy. In other words, the efficacy of trans-Tenon’s retrobulbar triamcinolone infusion was the same. However, we suspect that the recurrence rate after triamcinolone infusion may be different, and we are currently investigating this possibility.

Owls’ eyes move
“Double crossed,” the cover illustration and article by Schwab on the barn owl refers to the alleged immobility of the owl’s eyes. This is a myth which should not be perpetuated in the BJ0. The owl’s eyes do in fact move, and while the amount is not large, it is just enough for two papers on the subject. The phrase “nearly immobile” is preferable.

Elimination of avoidable blindness
The 56th World Health Assembly (WHA) considered the report on the elimination of avoidable blindness (doc A56/26) and urged Member States to: (1) Commit themselves to supporting the Global Initiative for the Elimination of Avoidable Blindness by setting up a national Vision 2020 plan by 2005; (2) Establish a national coordinating committee for Vision 2020, or a national blindness prevention committee to help implement the plan; (3) Implement the plan by 2007; (4) Include effective monitoring and evaluation of the plan with the aim of showing a reduction in the magnitude of avoidable blindness by 2010; (5) To support the mobilisation of resources for eliminating avoidable blindness. The WHA also urged the Director-General to maintain and strengthen WHO’s collaboration with Member States and the partners of the Global Initiative for the Elimination of Avoidable Blindness as well as aid in the coordination and support of national capability.

4th International Congress on Autoimmunity
The 4th International Congress on Autoimmunity will take place 3–7 November 2004 in Budapest, Hungary. The deadline for the receipt of abstracts is 20 June 2004.
