Gremlin gene expression in bovine retinal pericytes exposed to elevated glucose

R Kane, L Stevenson, C Godson, A W Stitt, C O’Brien

Aim: To assess the influence of high extracellular glucose on the expression of the bone morphogenetic protein (BMP) antagonist, gremlin, in cultured bovine retinal pericytes (BRPC).

Methods: BRPC were cultured under conditions of 5 mM and 30 mM d-glucose for 7 days and total RNA was isolated. Gremlin mRNA levels were correlated, by RT-PCR, with other genes implicated in the pathogenesis of diabetic retinopathy and the signalling pathways in high glucose induced gremlin expression were probed using physiological inhibitors. Gremlin expression was also examined in the retina of streptozotocin induced diabetic mice.

Results: High glucose stimulated a striking increase in BRPC gremlin mRNA levels in parallel with increases in mRNA for the growth factors vascular endothelial growth factor (VEGF), transforming growth factor β (TGFβ), and connective tissue growth factor (CTGF) and changes in other genes including fibronectin and plasminogen activator inhibitor-1 (PAI-1). High glucose triggered gremlin expression was modulated by anti-TGFβ antibody, by the uncoupler of oxidative phosphorylation, CCCP, and by inhibition of MAP-kinase (MAPK) activation. Striking gremlin expression was observed in the outer retina of diabetic mice and also at the level of the vascular wall.

Conclusions: Gremlin gene expression is induced in BRPC in response to elevated glucose and in the retina of the streptozotocin induced diabetic mouse. Its expression is modulated by hyperglycaemic induction of the MAPK, reactive oxygen species, and TGFβ pathways, all of which are reported to have a role in diabetic fibrotic disease. This implicates a role for gremlin in the pathogenesis of diabetic retinopathy.

D iabetic retinopathy is one of the most frequent causes of blindness in the working-age population. There is a strong and consistent relation between hyperglycaemia and the incidence and progression of diabetic retinopathy. Clinical studies have reported that the normalisation of glycaemia control can prevent diabetic microangiopathies and possibly cardiovascular complications. Several mechanisms exist by which hyperglycaemia results in retinal damage, including increased polyol pathway, activation of protein kinase C (PKC), increased non-enzymatic glycation, and generation of reactive oxygen species (ROS) by oxidative stress. Furthermore, other mediators, including growth factors such as vascular endothelial growth factor (VEGF), platelet derived growth factor (PDGF), and transforming growth factor β (TGFβ) contribute to the pathological manifestations of diabetic retinopathy, including basement membrane thickening, vessel occlusion and retinal hypoxia, which induces neovascularisation (reviewed by Cai and Boulton). New vessels and connective tissue grow on the surface of the retina or optic nerve head and into the vitreous. Visual loss at this time results from vitreous haemorrhage or fluid exudation from fragile new vessels.

Retinal pericytes are smooth muscle-like cells with attenuated processes enveloping the abluminal surface of microvessels and sharing a common basement membrane with the underlying endothelium (reviewed by Diaz-Flores et al). Pericytes express α smooth muscle actin (α-SMA) and have been implicated to have a contractile function, thus regulating blood flow. They are proposed to regulate microvascular angiogenesis and synthesise components of the vascular basement membrane. Pericytes have been demonstrated to be involved in the regulation of endothelial cell number and morphology and microvessel architecture. One of the first histological features of diabetic retinopathy is the loss of retinal pericytes.

Gremlin is a member of the differential screening-selected gene aberrative in the neuroblastoma (DAN) family of bone morphogenetic protein (BMP) antagonists. The protein is highly conserved through evolution and contains a cysteine rich region, a cysteine knot, which is also shared by members of the TGFβ family, PDGF family, nerve growth factor, and other secreted proteins. Gremlin exists as both secreted and cell associated forms. It can be post-translationally modified by glycosylation and phosphorylation. Gremlin influences diverse processes in growth, differentiation, and development.

Gremlin has been demonstrated to antagonise the activities of BMP-2, BMP-4, and BMP-7. It does this by direct binding to and heterodimerisation with the BMP. This then results in these BMP ligands failing to bind their receptors, which are members of the TGFβ receptor superfamily. Increased expression of gremlin has recently been demonstrated in several models of diabetic nephropathy, pointing to a role for gremlin in diabetic fibrotic disease. In this study, we explore gremlin expression in a model of diabetic eye disease, using BRPC cultured in high glucose levels. We also examine in vivo gremlin expression in the retina of C57 mice with streptozotocin induced diabetes.

Abbreviations: α-SMA, α smooth muscle actin; BMP, bone morphogenetic protein; BRPC, bovine retinal pericytes; CCCP, carbonyl cyanide m-chlorophenylhydrazone; CTGF, connective tissue growth factor; DAN, differential screening-selected gene aberrative in the neuroblastoma; EST, expressed sequence tag; MAPK, MAP-kinase; PAI-1, plasminogen activator inhibitor-1; PDGF, platelet derived growth factor; PKC, protein kinase C; ROS, reactive oxygen species; RT-PCR, reverse transcription-polymerase chain reaction; TGFβ, transforming growth factor β; VEGF, vascular endothelial growth factor.

METHODS

Cell culture

Bovine retinal pericytes (BRPC) were cultured in MCDB 131 (Invitrogen) supplemented with 2 mM l-glutamine and 5% fetal bovine serum (passages 5–7), and maintained in medium containing either 5 mM or 30 mM D-glucose for 7 days. Culture medium was replenished twice during this period to maintain glucose levels in the desired range. For the low/high glucose experiments (n = 3) BRPC were cultured in 5 mM glucose, 30 mM glucose, or 5 mM glucose and 25 mM mannitol (as an osmolarity control) for 7 days. To examine regulation of gremlin expression BRPC were cultured in 30 mM glucose plus 10 μM PD 98059 (Calbiochem), or 10 μM GF 109203X (Calbiochem), or 500 nM CCCP (Sigma), or 1 μg/ml αTGFβ1 antibody (R&D Systems) for 7 days. PD 98059 is a selective inhibitor of MEK23 that acts by inhibiting activation of MAPK and subsequent phosphorylation of MAK substrates. GF 109203X is a selective PKC inhibitor.24 CCCP (carbonyl cyanide m-chlorophenylhydrazone) is an uncoupler of oxidative phosphorylation.25 αTGFβ1 antibody neutralises the bioactivity of TGFβ1.26 BRPC were also cultured in 5 mM glucose with 10 ng/ml TGFβ1 or 10 ng/ml TGFβ2.

RNA extraction and reverse transcription-polymerase chain reaction

RNA was extracted from BRPC using Trizol (Invitrogen) according to the manufacturers' instructions. RT-PCR (reverse transcription-polymerase chain reaction) was performed as follows: 2 μg of total RNA was treated with DNaseI and random primers and Superscript II (Invitrogen) using the manufacturer’s protocol. Limited cycle PCR was carried out using the following primers: VEGF; sense 5′-GGA TCA AAC CTC ACC AAA GC-3′, antisense 5′-GAG CAT TGT TCT GTC GAT GG-3′, CTGF, sense 5′-GAA AGG CAA AAA GTG CAT CC-3′, antisense 5′-CTT CGA CTG AAA TCA CG-3′, TGFβ1, sense 5′-TGA TGT CAC CGG AGT TGT GC-3′, antisense 5′-TCC AGG CTC CAA ATG TAG GG-3′, Fibronectin, sense 5′-CAC TGC CCA CTA CCA CG-3′, antisense 5′-ATG GAT CCC AAT CCA AAT CC-3′, PAI-1, sense 5′-TGA CCA CAG GAG GAA AAA AA-3′, antisense 5′-GTT GTT TGA TCT GGG AGG G-3′. Bovine gremlin was amplified using the primers sense 5′-CTT CCA GGA GGA GCA CTC-3′, antisense 5′-TGG ATG GAA TCT GTC CG-3′, where Y = C or T, R = A or G. As a control for equal amounts of RNA, either 18S rRNA or the housekeeping gene GAPDH was amplified. 18S, sense 5′-GGT GAT GCT GGT GCT GAG TA-3′, antisense 5′-GTT GTT TGA TCT GGG AGG G-3′. The expression of growth factor genes suggested to be involved in the pathogenesis of diabetic retinopathy, such as VEGF, TGFβ, and CTGF28–31 were examined. Figure 1 shows the results of RT-PCR for glucose induced gene expression in BRPC. All three growth factor genes examined, VEGF, CTGF, and TGFβ1 were expressed. Two alternatively spliced forms of bovine VEGF were expressed; VEGF 164 (orthologue of human VEGF 165) and VEGF 120 (orthologue of human

Animal model and immunohistochemistry

The animal model is as described by Cox et al.28 Briefly, male c57Bl/6 mice (20–25 g at 5–6 weeks old) were randomly assigned to non-diabetic control or diabetic groups. Diabetes was induced by a single intraperitoneal injection of streptozotocin (Sigma) at 180 mg/kg bodyweight. Control animals received an equivalent dose of the drug vehicle (citrate buffer at pH 4.6). The mice were caged individually and allowed food and water ad libitum. Blood glucose levels were measured fortnightly. Diabetic animals with blood glucose levels between 20 mM and 30 mM were included in the study. Groups of 8–10 animals were taken for each experimental and control group and the experiment was carried out three times. All animals were sacrificed after 8 weeks’ duration of diabetes.

An anti-gremlin antibody was generated by Fusion Antibodies (Belfast). Sections of mouse eyes were de-waxed and rehydrated in PBS. The sections were then subjected to antigen retrieval for 20 minutes in citrate buffer (pH 6.0) in a pressure cooker. After washing in PBS, the sections were blocked with 5% normal goat serum, 1% BSA, 0.01% Triton-X100 and incubated in primary antibody to gremlin at 1:100 dilution overnight at 4°C. Controls were performed using primary antibody exclusion and rabbit non-immune serum. Before detection using the anti-rabbit Envision+System (Dako Ltd.), endogenous peroxidase activity was quenched in 3% hydrogen peroxide. After allowing dianaminobenzidine reaction product to develop, the sections were then washed extensively, counterstained with haematoxylin, and mounted with Glycermount (Dako Ltd).

RESULTS

Glucose induced growth factor gene expression in BRPC

The expression of growth factor genes suggested to be involved in the pathogenesis of diabetic retinopathy, such as VEGF, TGFβ, and CTGF28–31 were examined. Figure 1 shows the results of RT-PCR for glucose induced gene expression in BRPC. All three growth factor genes examined, VEGF, CTGF, and TGFβ1 were expressed. Two alternatively spliced forms of bovine VEGF were expressed; VEGF 164 (orthologue of human VEGF 165) and VEGF 120 (orthologue of human...
Figure 2: Gremlin is upregulated in glucose in BRPC. (A) RT-PCR analyses of quantitatively standardised total RNA samples from BRPC cultured in 5 mM glucose, 5 mM glucose, and 25 mM mannitol (as an osmolarity control), or 30 mM glucose for 7 days. SDW was used as a negative control instead of cDNA and is indicated by -. 18S ribosomal RNA was used as a control for equal input amounts of RNA. (B) The bovine Gremlin PCR product was subcloned in to the vector pCR2.1 RNA was used as a control for equal input amounts of RNA.

**DISCUSSION**

Within the retina, pericytes provide vascular stability, exert control over endothelial cell proliferation and morphology, and microvessel architecture. 14

Multiple growth factors are involved in the regulation of the retinal vasculature, and are also involved in the pathogenesis of diabetic retinopathy. We have demonstrated in this study the increased expression of the profibrotic growth factors, CTGF and TGFβ, and the angiogenic factor VEGF in retinal pericytes exposed to high concentrations (30 mM) of extracellular glucose. CTGF is a novel, cysteine rich secreted protein, which is implicated in fibrotic disorders and has been associated with proliferative retinopathies. 15 16

More recently, other studies show increased expression of CTGF in the diabetic retina 37 and demonstrate the expression of CTGF in pericytes and point to a role for CTGF in diabetic retinopathy. 38 High glucose induced CTGF expression has been associated with proliferative retinopathies. 35 36

Gremlin expression was measured by RT-PCR (fig 3A). Culturing BRPC in 30 mM glucose and αTGFβ1 antibody abolishes gremlin expression. Culturing BRPC in 30 mM glucose and PD 98059 or CCCP reduces gremlin expression, therefore implying the MAPK pathway and hyperglycaemia induced ROS in regulation of gremlin expression in this model. To determine if gremlin was directly regulated by TGFβ1 in BRPC, the cells were cultured in 5 mM glucose and 10 ng/ml TGFβ1, and 5 mM glucose and 10 ng/ml TGFβ2. Again gremlin expression was examined by RT-PCR and was found to increase with both TGFβ1 and TGFβ2 stimulation (fig 3B).

**Gremlin is expressed in the retina of diabetic mice**

Gremlin immunoreactivity was localised to the nerve fibre layer, ganglion cell layer and inner plexiform layers in the retina of both non-diabetic (fig 4A), and diabetic mice (fig 4B). The diabetic animals also demonstrate gremlin immunoreactivity in the outer retina (fig 4B), and also at the level of the vascular wall (arrow)—especially noticeable in the large retinal vessels (fig 4C).
Gremlin gene expression in bovine retinal pericytes

Gremlin gene expression in bovine retinal pericytes may contribute to the pathogenesis of diabetic retinopathy. Pericytes occur in response to elevated glucose levels and concomitant overexpression of growth factors by retinal cultures of endothelial cells and pericytes has been demonstrated to inhibit retinal endothelial cell proliferation. We have demonstrated in this study direct induction by high glucose of these growth factors, VEGF, CTGF and TGFβ, thus demonstrating that concomitant overexpression of growth factors by retinal pericytes occurs in response to elevated glucose levels and may contribute to the pathogenesis of diabetic retinopathy.

Hyperglycaemia induces basement membrane thickening in the diabetic retina and this may contribute to the closure of capillaries. Increased coagulation and contractility are also associated with diabetic retinopathy. We have demonstrated here that when exposed to elevated levels of glucose, retinal pericytes increase fibronectin and PAI-1 expression. Increased CTGF levels may also contribute to increased matrix deposition. Pericytes may also contribute to the process of basement membrane thickening by secreting fibronectin. Fibronectin mRNA elevation has previously been demonstrated in pericytes in response to 22 mM glucose, and we demonstrate increases following exposure of pericytes to 30 mM glucose.

There exists an emerging paradigm that patterns of developmental gene programs reappear in the context of a disease process. This may attempt to repair or regenerate tissue. It is also possible that this execution of a developmental program may contribute to the disease process. One of these developmental genes is gremlin. Increased expression of gremlin has been recently demonstrated in models of fibrotic disease processes, most notably diabetic nephropathy. We have also demonstrated in this study that increased gremlin expression is associated with retinal pericytes exposed to high extracellular glucose. We have shown that gremlin expression in retinal pericytes can be abolished by culturing pericytes with TGFβ1 or TGFβ2, therefore implying this signalling pathway in gremlin expression.

Gremlin gene expression is induced in response to high glucose in this system. Its expression is modulated by the MAPK, ROS, and TGFβ pathways, all of which are reported to have a role in the pathogenesis of diabetic retinopathy (reviewed by Brownlee). The concomitant increased expression of multiple profibrotic genes and gremlin in retinal pericytes exposed to 30 mM glucose, and regulation of gremlin expression by the profibrotic cytokine, TGFβ, may imply a role for gremlin in fibrogenesis. Gremlin is a 184 amino acid protein and a member of the cysteine knot superfamily. The protein is highly conserved during evolution and is present in soluble and cell associated forms. It belongs to a novel family of bone morphogenetic protein (BMP) antagonists that includes the head inducing factor Cerberus and the tumour suppressor DAN. These proteins have important roles in limb development and neural crest cell differentiation. Gremlin expression can be induced in mesangial cells in response to elevated glucose, TGF-β, and cyclic mechanical strain. A pathogenic role may be attributed to gremlin in the context of diabetic nephropathy as overexpression of gremlin induces transdifferentiation of cultured tubular epithelial cells to a more fibroblast-like phenotype. We have observed in this study that gremlin protein expression in BRPC is both cell associated and secreted. As a cell associated protein it may function to alter gene expression and signalling pathways, as demonstrated by Chen et al. in tumour derived cell lines. Gremlin also functions as a secreted protein and in addition we have shown in this study that gremlin is expressed in the retinas of both non-diabetic and diabetic mice, and that expression
in the outer retina and the vascular wall of diabetic animals. Mathura et al. demonstrated high expression of BMPs in the adult outer retina, more specifically the RPE, and suggest that both BMP-2 and BMP-4 may serve as negative growth regulators in the retina. The expression of gremlin in the vascular endothelium is significant as this may contribute to proliferation of the vascular endothelium. Trousse et al. demonstrate how BMP-4 mediates apoptosis in the retina, and this may be antagonised by Noggin, another member of the BMP antagonist family. As gremlin is a known antagonist of BMPs, it may have a role in proliferation by antagonising the antiproliferative effects of BMP in the retina. Therefore, modulation of BMP expression may have a role in proliferative retinopathies.
