process. In addition, impression cytology can be used to monitor recurrences in patients with previously treated OSSN in the outpatient setting.

Although impression cytology only allows sampling of the superficial cell layers, the sensitivity of this technique has been documented at 70% when the lesion is found to be invasive by histology. Consequently, some invasive lesions may still be missed. We anticipate that there are likely to be further improvements to the technique of impression cytology to make it more logis-
tically simple and less time-consuming, with perhaps an increase in sensitivity. In the meantime, we agree that it is a useful, often underused, complementary investigation in the management of OSSN.

REFERENCES

In the credit for the December 2007 cover “The Royal College of Ophthalmologists” was incorrectly referenced as “The Royal College of Ophthalmology”. In addition the following information should have been published about the cover image:

The double wheel Phoropter was made by Davidson & Co of Great Portland Street, London in about 1902. It is made of a wood surround which holds in the lenses the whole mounted on a brass stand. It was designed to facilitate the easy and quick introduction of a range of lenses for retino-
scopy. Similar models had a chin rest for the patient and a reading chart suspended from the front of the instrument stand. The firm of Davidson made a range of testing room equipment including a perimeter, a mono-
cular microscope of 30× magnification and a Worth-Black amblyoscope.
